COLLEGE OF NURSING: APPLICATION FOR CHARTER.—A petition of the College of Nursing, Ltd., f a Royal Charter was heard on Feb. 29th by a Committ of the Privy Council consisting of Lord Warrington Clyffe, Sir Maurice de Bunsen, and the Lord Advocat On behalf of the College Mr. R. Mitchell Banks stated th the College, which was incorporated in March, 1916, h been founded to promote the better education and trainir of nurses and the advancement of nursing as a professio and was precluded from applying its funds for profit earnir The membership at present stood at 26,300, admission membership being limited to those entitled to have th names on the State Register, and the College did n propose to compete with or set up any substitute for t General Nursing Council. The College possessed lecture ha and laboratories and was in a sound financial position, anonymous donor having subscribed £100,000. Oppositi came from the Royal British Nursing Association, t Scottish Nurses' Association, the Poor-Law Officers' Unic and the Association of Hospital Matrons. Mr. Gav Simonds put the case on behalf of the opposing bodi submitting that the College had not performed su signal services as would justify the granting of a chart After hearing the arguments Lord Warrington sa that the Committee would report in favour of the Colleg the draft charter, however, would require amendme particulars of which would be communicated in d course.

Correspondence.

"Audi alteram partem."

THE POSITION OF THE VOLUNTARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—The correspondence in your columns on the voluntary hospitals has led me to consider the hospital situation as it exists to-day in my home city, and to ask myself what really—sentiment apart—there may be in the voluntary system to make us desire its continued existence.

A modern voluntary hospital may be likened to a garage for the reception of damaged human automobiles, equipped with a sufficient staff of skilled artificers whose aim it is to investigate the defects of the damaged human beings and to make as many as possible of them "fit for the road" again. As methods of investigation and treatment have been more and more elaborated it has been found necessary to add to the number of the artificers. At the Bradford Royal Infirmary with 210 beds there is to-day a visiting staff (not including honorary anæsthetists) of 17, or one for every dozen patients.

The usual poor-law hospital has never been staffed on these lines. On the outskirts of Bradford to-day there is a large poor-law hospital—a modern building with excellent wards containing several hundred beds. The medical staff consists of a solitary general practicioner who adds the medical charge of the hospital patients to his family practice. And consequently investigation and active treatment cannot be carried out in such hospitals, whose inmates are either derelicts or such as chiefly require nursing care. Public bodies have been for a good many years past gradually waking up to the need for, at any rate, an approximation to the ideal of fitting the damaged automobile for the road again. Early in this century the Bradford board of guardians changed the title of their hospital from poor-law hospital to St. Luke's Hospital. And they were fortunate enough to secure as medical superintendent a man with surgical experience gained in more than one large voluntary hospital. This surgeon, being also an able administrator and a glutton for work," was able, with the aid of two resident medical officers, to do a considerable amount of "refitting" work for his patients. The result was the raising of St. Luke's Hospital's status much above that of all but a very few poor-law hospitals in the country. The hospital during the war was handed over to the War Office and its bed accommodation largely increased. After the war it was leased to the City Council and became the first municipal hospital in this country, a hospital which is now doing an immense amount of excellent refitting work.

I desire shortly to compare and contrast the (voluntary) Bradford Royal Infirmary with the (municipal) St. Luke's Hospital in order to discover whether the one is in any way capable of giving superior service to the community to the other. The efficiency of a repairing garage must depend upon (1) a sufficient supply of skilled artificers, (2) adequate opportunities for the training of these artificers, and (3) a management willing to and capable of providing the plant and appliances necessary for the work.

(1) As regards staff, at the infirmary there is a visiting medical staff of specialists in the ratio of 1 to 12 or 13 patients; at St. Luke's Hospital the medical staff (excluding residents) is 1 for every 50 to 60 patients.

(2) As at voluntary hospitals generally there is what may be termed an apprenticeship system in force at the infirmary. Before I was appointed to the charge of inpatients I had served as a resident for three years and as an honorary assistant surgeon for seven years. There is no assistant staff at St. Luke's Hospital and (resembling, I believe, in this respect all public authority general hospitals) that post-graduate experience has been gained by the various members of its staff has been obtained at the voluntary hospitals. The desirability of such training does not appear to have been realised and no provision for it has been made.

(3) But the chief difference between the two hospitals is in the lay managements and their relations to the medical staffs. In the voluntary hospital every member of the board may be assumed to be an interested sympathiser, since he or she has voluntarily accepted the duties of the office. The board meetings are held on the infirmary premises; the house committee meets there each week and at each of these weekly meetings there are not only members of the medical staff present, but the matron and the senior resident officer attend at the end of each meeting and are given the opportunity of bringing up for discussion any matter which either of them may desire to ventilate.

The governing body of St. Luke's Hospital is the City Council's Health Committee, and the affairs of the hospital appear as one item on a long agenda at meetings which are never held at the hospital. I have it on the authority of another corporation chairman of committee that only the chairman and deputy chairman of any committee are ever in a position to be au fait with the details of its departmental business. And I am very certain that most of the members of the Bradford Health Committee have never been even once "round the St. Luke's Hospital."

Moreover, the notion (one which underlies not a little of industrial unrest) that no paid member of a staff has any right to a say in the management, operates so that the members of the St. Luke's visiting staff are never consulted—never have any opportunity to confer with the health committee, and so are not in a position to guide these laymen with regard to what is required to keep the hospital "up to date."

The critics of the voluntary hospitals make the financial difficulty the burden of their cry. And in theory, with the city rates available, the City Hospital should be in a vastly superior position for providing the increasingly costly additional accommodation and equipment. But what has actually occurred in Bradford? Since 1921 the board of the Bradford Royal Infirmary has not only raised over £200,000 towards the cost of a new infirmary, but has built a nurses' home costing £30,000 and spent over £5000 on extension of the X ray department and nearly £1000 on extensions of the pathological and massage departments. Whereas, quite a number of improvements have been greatly needed at St. Luke's Hospital, which no party in the City Council dares to advocate because to carry out the work would inevitably require an addition to the rates.

And so my survey of the hospital situation in Bradford leads me very definitely to the conclusion that, whatever theorists may say, at present, in this city at any rate, the voluntary hospital as compared with the municipal hospital has (1) a relatively bigger staff (whose members are consequently able to devote more individual attention to their patients), (2) greater opportunities for the junior members of the staff to receive supervised training and experience, and (3) a board of management probably much more intensely interested in the work of the hospital and certainly much better able to supply the wherewithal required for institutional treatment.

Finally, I would again lay emphasis on the point that it is infinitely more easy to convince a small body of interested people of the need for expenditure on improvements and extensions than it is to persuade the members of an elected public body (however convinced they may be of the value of the suggested outlay) to risk their seats by voting for an increase in the rates.

I am, Sir, yours faithfully,

Bradford, Feb. 28th, 1928. JAMES PHILLIPS.

THE TREATMENT OF BURNS BY TANNIC ACID.

To the Editor of THE LANCET.

SIR,—I was interested to read in your issue of Feb. 18th (p. 336) the remarks of Dr. R. M. Gordon on the Treatment of Burns by Tannic Acid and also the annotation on that subject. I should like to stress the value of this method of treatment, which to my mind is far the most important advance as yet made in the treatment of burns and scalds. I am only surprised that the method is not more widely used, for not only is it definitely a life-saving measure, at any rate in

children, but the resulting scar is superior to that produced by any other form of dressing, while the method of application is comparatively simple.

Since the publication of the excellent article by E. C. Davidson [1] in August, 1925, I have used this method in my department of the Royal Edinburgh Hospital for Sick Children, and I have personally dealt with 38 cases of burns and scalds in young children. I will not enumerate here the many advantages that I have noticed in comparing tannic acid to such applications as picric acid, ambrine, adrenalin soaks, saline baths, and so forth, which I had used formerly, but I should like to draw attention to the very marked improvement in the death-rate. J. Fraser, working in the same hospital, quotes a death-rate of 38·7 per cent. for all cases, while during the last two and a half years I have lost only three patients in 38 cases—a case-mortality of 7·9 per cent. —and from the experience of six years previous to the introduction of this method I can assert that there has been little difference in the severity of the cases admitted, both as regards surface area and depth. In addition, the length of stay in hospital has markedly diminished and it is rare that skin grafting is required.

As regards the actual method of application, we have gradually modified Robertson's original method and we have found the most satisfactory technique to be as follows :—

1. A hypodermic injection of heroin is given if the burn is extensive.
2. The area is cleaned with methylated spirit and blisters are snipped and removed.
3. A *freshly* prepared aqueous solution of 2·5 per cent. tannic acid is sprayed on the surface, and this is repeated hourly for about eight hours until the coagulum shows a light brown tint which is steadily deepening.
4. The child is placed in an electric cradle to keep up the body warmth and to dry the wound, which is exposed to the air without any form of dressing. It is important that if at all possible no part of the burnt area should touch the bedclothes or bed, in order to get a complete coagulum.
5. The general treatment adopted consists in slight stimulation and the forcing of fluids by mouth, rectum, and skin if necessary.

It will be found that the coagulum steadily deepens in colour until it is almost black, and in the majority of cases this will remain absolutely dry. It begins to separate at the end of a week as a rule, and has generally become completely detached in 10 to 16 days, after which any simple ointment is applied. Most cases are discharged from hospital in 10 to 14 days. The child usually is extremely comfortable and does not pass through the ordinary toxic stage so commonly met with in severe burns, and the condition rarely gives rise to any anxiety.

I am, Sir, yours faithfully,

GERTRUDE HERZFELD,
Surgeon to the Royal Edinburgh Hospital for Sick Children.

Feb. 22nd, 1928.

THE EMPLOYMENT OF TUBERCULOUS PATIENTS.

To the Editor of THE LANCET.

SIR,—I am glad to see attention being paid to this subject. Very many patients make a conditional recovery under sanatorium treatment, but while money is spent freely in providing this, no corresponding effort is made to provide the necessary after-conditions. These include the observance of a few simple rules, home quarters modified on sanatorium lines—not necessarily expensive, though not possible everywhere—and remunerative employment, or its equivalent. Those who are lucky enough on leaving a sanatorium to find these conditions provided may live for years in health, leading useful lives ; but these form a small minority. As a rule the convalescent is again ruined in health, mainly by semi-starvation through lack of employment. Owing to the exaggerated fear of infection, which wide experience (including that of Dr. Varrier-Jones's own colony) proves to be harmless if simple precautions are observed, even sputum-negative convalescents of exceptional abilit and character are refused employment. Failin ordinary ways three others are possible : home-work special workshops under medical supervision (a advocated by the late Dr. F. S. Tinker), and tuber culosis colonies on the pattern of Papworth. Each o these has its part to play, but they all need organising The lack of them is causing a great waste of publi money and much avoidable suffering.

I am, Sir, yours faithfully,

Farnham, March 5th, 1928. F. R. WALTERS.

MENTAL BREAKDOWN IN ADOLESCENCE.

To the Editor of THE LANCET.

SIR,—In the annotation on this subject in you issue of Feb. 25th it appears to me that you fall int the very error which you say should be avoided. Th discussion at the Maudsley Hospital was on th prognosis of acute schizophrenia. You state of thos cases which recover that "to describe them a dementia præcox is misleading" and that such young person "ought not to be branded for life as dement." The remedy is obvious ; he can b designated a recovered schizophrenic. The objection to the term "dementia præcox" are many, we known, and need no recapitulation. The popular anc I take it, the usual medical connotation of the ter "dementia" implies principally an intellectua determination, and though such determinatio undoubtedly does occur in schizophrenia, it is ofte more apparent than real, and appears to be funda mentally determined by emotional causes and t depend in essence on a withdrawal of interest from th outside world. It is a commonplace of psychiatr experience to find a surprising revival of intellectua performance in the most "hopeless dement" whe suffering from an acute physical disorder.

Quite a number of puerperal (as well as many othe cases show an acute schizophrenic reaction, and y (from a social point of view) recover completely. T adopt the view that if they recover they could n have been cases of schizophrenia appears to me simpl to beg the question completely and to imply tha diagnosis in mental disease is dependent not o clinical acumen but on end-results. Admittedly, ou powers of prognosis in this disorder are poor, but th line of argument adopted in your annotation appea not only to lead nowhere—a sad but not uncomm phenomenon in psychiatric discussions—but, what far more serious, to deny the facts of observation.

I am, Sir, yours faithfully,

J. B. STRAFFORD LEWIS.

Colney Hatch Mental Hospital, New Southgate, March 2nd, 1928.

CARBON DIOXIDE IN ANÆSTHESIA.

To the Editor of THE LANCET.

SIR,—May I thank Dr. Ross Mackenzie for h letter in your last issue and state that I think th freedom I have experienced from respiratory-cent anxieties during anæsthesia must be very largely d to having avoided, for many years, the use of morph as a preoperative medication, except in administr tions of gas-and-oxygen in adults.

I am, Sir, yours faithfully,

JOSEPH BIRT.

St. James's Court, S.W., March 5th, 1928.

PUERPERAL SEPSIS.

To the Editor of THE LANCET.

SIR,—Mr. Bonney's address in your last issue most valuable and instructive. I would like to poi out that the folds between the outer and inner lab should receive very special attention in order to less the chances of sepsis taking place. It is not so easy clean them in a surgical sense as it is to deal with t ano-perineal region, but they are of equal importanc A good light is imperative and undue haste should

avoided. The result of neglect is that it is only too easy for the examining finger or the forceps blade to carry infection to the upper part of the vagina with disastrous after-effects. Nurses and practitioners alike should spare no pains in their effort to secure asepsis. I am, Sir, yours faithfully,

JAMES G. MACASKIE, L.R.C.P. & S. Edin.

London, W., March 3rd, 1928.

GASTRO-DUODENAL ULCERATION.

To the Editor of THE LANCET.

SIR,—Although when I wrote my letter I had not seen Dr. Hurst's 1920 article, I am sorry he should have inferred from it that I suggested Prof. MacLean was the introducer of alkaline treatment in gastric ulcer. I could not do so. At the same time I do think the latter put the treatment clearly for the use of the practitioner and so far as I knew he was the first to do so. It would be most unfortunate should the patients be frightened off by the possibility of an alkalosis, the diagnosis of which is admittedly difficult. Dr. Hurst also mentions the danger of alkalis in slight renal inefficiencies, but if, as it would appear, he relies on a urea test to avoid that danger, then he must give alkalis to all these cases, for urea does not expose slight inefficiency. If Dr. Hurst is right in his theory of alkalosis appearing only in private cases, it is strange; mine have all been private cases. The warning of alkalosis has already had an unfortunate effect. I saw a case last week whose own doctor had advised alkali, but directed it in very tentative fashion, suggesting a fear to the patient. This treatment should be given adequately or not at all.

I am, Sir, yours faithfully,

A. J. D. CAMERON, M.B., Ch.B.

Northampton, March 5th, 1928.

To the Editor of THE LANCET.

SIR,—Dr. Hurst's letter, which appeared in your issue of March 3rd, implies that Dr. Cameron's letter published on Feb. 25th suggested that I was the first in the country to write on the intensive alkaline treatment of ulcer. There is no such suggestion in Dr. Cameron's letter. That I and my colleagues have brought forward concrete evidence of the value of this treatment is all that is claimed. Like Dr. Hurst and many others, I have used large doses of alkali at least 15 years ago. Questions of priority do not really interest me.

In our original paper it was stated that alkalosis is a bogy which need not be feared. I drew attention to the fact that very large doses of alkali might not be advisable in patients suffering from advanced renal lesions. Dr. Hurst states that alkalies are dangerous "with renal insufficiency which may be so insignificant that it can only be recognised by estimating the blood-urea." Unfortunately for this assertion, it is now quite well understood that changes in blood-urea are obtained only in advanced cases of nephritis; estimation of blood-urea is of no value in mild cases and gives no information in such cases. With regard to the alleged danger of giving alkali to patients suffering from advanced pyloric stenosis, I may say that I have repeatedly given alkali to such patients with no untoward results of any kind. Space forbids a full discussion of this subject at present, but I have treated the matter at length in a lecture on the Medical Treatment of Gastro-duodenal Ulceration delivered to the local branch of the British Medical Association at Canterbury. This lecture will be published very shortly. It is true that my personal observation has been practically confined to hospital cases, but I have talked to many of our staff, as well as to former students and to several general practitioners who are using the method. Not one of these has ever had the slightest difficulty. In my ward at the present time there is a patient who was treated by intensive alkaline treatment in another clinic. This patient had a letter, in which it was stated that alkaline treatment had been tried, but had to be discontinued because of the appearance of symptoms of alkalosis. We gave the usual alkaline treatment, but no signs of alkalosis appeared. This patient is now rapidly progressing towards recovery. It would be nothing less than a tragedy if the practitioner were to be prevented from using this treatment for fear of so-called alkalosis, a condition which under the circumstances of the treatment and with healthy patients is more theoretical than real.

Dr. Hurst's statements regarding the neutralising value of the various doses of alkali used are, of course, correct. Sodium citrate has been used instead of sodium bicarbonate by several physicians for many years. Bismuth oxycarbonate neutralises only very slowly and to a limited extent under the conditions of acid concentration likely to be met with in the stomach. It is, however, useful for controlling diarrhœa when this is present. Very often I use a powder which contains only 1 part of bismuth oxycarbonate in 13 parts of the powder. At present we need not trouble about complicated physico-chemical and biochemical considerations governing the correct dosage of alkali. The correct dose for practical purposes is that which controls the acidity and allows of a fairly regular action of the bowels. Beyond this, in the present state of our knowledge, it is not necessary to go. As far as teeth are concerned, might I point out that in the original paper the following sentence occurred: "Of course, it goes without saying that defective teeth should be attended to."

The intensive alkaline treatment gives such excellent results that it should be used by every general practitioner in the country. No special supervision or knowledge is necessary; many patients do quite well while at work. Its application is now so simple that it hardly inconveniences the patient.

I am, Sir, yours faithfully,

London, March 5th, 1928. HUGH MACLEAN.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Hurst's letter that our observations are restricted to patients of the hospital class, may I say that I have examined many private patients, and that the results have been the same as those seen in the hospital. No symptoms attributable to the alkali were encountered. I have examined many patients under varying forms of treatment, and I have found universally that only those treated by the intensive method achieved the desired results in a short time, many of the others showing but varying degrees of improvement.

With regard to oral sepsis, it was assumed in our paper that the present-day practitioner was sufficiently conversant with modern practice not to overlook such an obvious possibility of trouble. My experience has been that nearly all cases had been examined and treated for oral sepsis or had been advised to consult their dental surgeons. In some cases this had not been undertaken by the practitioner, as he had at once handed the patient on to the special department concerned, to be taken over in toto, and not because he had not taken the possibility into consideration.—I am, Sir, yours faithfully,

London, March 5th, 1928. GEOFFREY FILDES.

DR. MUTHU'S "PULMONARY TUBERCULOSIS."

To the Editor of THE LANCET.

SIR,—Being so far away I was not able to see before now your issue of Jan. 7th, which contains a review of my book on Pulmonary Tuberculosis. I consider your reviewer has done scant justice to my work, which he has handled rather roughly while missing its main theme and purport. For one thing he has not made much discrimination between theories and suggestions in the work, which are valuable only so far as they are pregnant with new ideas, and facts which I have adduced to prove some of my contentions. He talks irrelevantly about the "offspring pneumococcus" and "brother of the gonococcus." But brother or sister, he can neither refute nor

ignore the important experiments made by such men as Maher, Stockwell, Sweany, who have conclusively shown the intenability of constancy of type of tubercle bacilli and the existence of a certain relationship between them and Gram-positive granules, cocci, bacilli and even granular forms brought about by means of suitable cultural media.

I should have thought that the work of a reviewer is, instead of sitting in judgment as if he were an infallible pope, to place the salient points of a book before the readers and leave them to judge whether it is a "good" or a "bad" one. The burden of my volume is to emphasise :—

1. That the ætiology of tuberculosis lies deeper than infection with tubercle bacilli.

2. That social and economic conditions create or favour the disposition to disease.

3. That nutrition and environment, instead of being side issues, control tuberculosis more than infection, which only rears its head when health is impaired by poor nutrition and bad social and economic environment.

4. That in proportion as the nations stand high in their economic prosperity and well-being of their people have they reduced the incidence and mortality of tuberculosis.

The whole tenor of the review shows bias and want of sympathetic insight in my work, and it would be bad day if the fate of a new publication should depend upon the prejudiced opinion of one man who may or may not be qualified for his task, and who may shelter himself under an assumed name or remain anonymous.

Yours truly,

Egmore, Madras, Feb. 9th, 1928. C. MUTHU.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

REORGANISATION OF OFFICES (SCOTLAND) BILL.

ON Feb. 28th Sir JOHN GILMOUR (Secretary of State for Scotland) moved the second reading in the House of Commons of this Bill, which, he explained, provided that on the appointed day the Scottish Board of Health, the Board of Agriculture for Scotland, and the Prison Commissioners for Scotland should cease to exist. The powers and duties of these Boards, including the Prison Commissioners for Scotland, were to be transferred to and vested in a Department of Health for Scotland, a Department of Agriculture for Scotland, and a Prisons Department for Scotland, under the control and direction of one of His Majesty's Principal Secretaries of State, and consisting of a secretary and such other officers and servants as the Secretary of State may determine. The offices of the departments were to be situated in Edinburgh. The persons employed by the Board were to be transferred and attached to the department, and should be in no worse position as regards tenure of office, salary, and superannuation allowance than if the Bill had not passed. No vacancy in the office of member of the Scottish Board of Health existing at the passage of the Bill or afterwards was to be filled, and that part of Section 3 of the Scottish Board of Health Act, 1919, requiring that the Board of Health should at all times include certain members having the qualifications therein set forth was to cease to have effect. The right hon. gentleman said that the Bill was practically identical with that of last year. While it abolished patronage, the Bill did not lessen the possibilities of contact between outside interests in Scotland and the departments. The sole motive was one of efficiency. The Bill left intact the same responsibilities, and it gave to the Minister in charge in the House of Commons additional assistance in that, in future, he would have the valuable advice of first-class civil servants. There was no intention of transferring the work of the departments to London, and to make that clear he had inserted a provision in the Bill to the effect that the offices should be in Edinburgh.

Rejection Moved.

Mr. T. JOHNSTON moved the rejection of the Bill, and contended that although the offices would be in Edinburgh, the power that directed the departments would be in London. The Government were deliberately attempting to take away the administration of public affairs in Scotland from skilled men selected because of their specialised knowledge, and transfer them to men who, whatever scholastic qualifications they might have acquired at Oxford or Cambridge, had not proved their fitness to control the departments.

Mr. BARR seconded the rejection and Mr. WHEATLEY supported it.

Mr. SIDNEY WEBB urged the Government not to smother the real experts in these departments by administrative chiefs. He admitted that it would be to the advantage of the Minister to have an administrative chief in each department.

Mr. KIDD said that from his experience in the Board of Health there was probably no better service than that which was obtained in Edinburgh. There was, however, a great deal to be said for concentrated administration of the public service in the hands of the civil service.

The debate on the second reading was adjourned.

Administrative Efficiency.

The debate was resumed on Monday, March 5th.

Mr. SKELTON said that nobody had ever suggested that the administration of health and other things for which the Board of Health was responsible was less efficient in Scotland than in England. Neither in the Parliament of 1922 nor in this Parliament had there been a single question raised as to the administrative efficiency of the Board. If this Bill passed he did not believe that they would have first-class civil servants at the head of the departments in Scotland. He opposed the Bill because he was satisfied that the Government were taking a step which was unwise and unjustified and one which would not be of any essential use at all.

Dr. DRUMMOND SHIELS said that he opposed the Bill. It was an attempt in the name of efficiency, and with a timid suggestion of economy, to approximate the Scottish system of government to the English system. The Board system was a more democratic form of administration than the one-man system. A great part of the functions of Scottish boards was to deal with local authorities. Members of those boards were not simply secretaries and bureaucrats; they were people who, in many cases, had had outside technical and other training. Some of them had been actually members of local authorities, and had had to deal with local authorities. Such negotiations with local governing bodies constituted a very important element in Scottish administration and was a function much more suitable for a board than for a civil servant as head of a department. A Board was more impressive than a Secretary and had more human points of contact. It was true that the Board system, which included men who came in from the outside, involved patronage, but the nominations were made by the Secretary of State for Scotland, and it was not likely that that right hon. gentleman would nominate for these positions individuals who would be likely to damage the efficiency of his own departments, and do that for political reasons. It must be admitted, on the whole, that the men who had been appointed to these posts in the past had been able men. His fear was that under the Bill the higher posts would be filled from England. He was specially interested in the Scottish Board of Health. The Secretary of State for Scotland, speaking during the previous debate on this Bill, put a great deal of emphasis on the report of the Royal Commission which, he said, condemned the Board system in Scotland. But the Royal Commission was dealing with an entirely different kind of Board and was referring almost entirely to the Local Government Board. The Board of Health met at least once a week, and sometimes oftener, and had minutes kept of its proceedings. It was under the chairmanship of the Parliamentary Under Secretary for Scotland and was a very different Board from the old Local Government Board. On the present Board was the head of the National Health Insurance administration in Scotland, a representative of the legal department, and of the Pensions and Medical Departments. The appointment to the head of the Medical Department was likely to be vacant in a very few weeks. Who was going to be appointed to succeed the very distinguished present head of the department? There were men junior to him in that department who were suitable for that appointment and who were familiar with Scottish local government. Was one of those to be appointed or were they to have appointed to this important position in Scotland, requiring a very intimate knowledge of Scottish local authorities, an official from the English Ministry of Health? They must wait and see, but he was very suspicious that some change of that kind was likely to take place. The heads of the Scottish Medical Department and the junior medical officers had been in the past men who had been medical officers of health in important towns in Scotland. The House, he thought, would agree

at a man who had had experience of the work of a medical ficer of health in some of the large towns of Scotland was ie proper type of man to be at the head of their national edical department. The Bill took away some of the last aces of Scottish individuality and sentiment from the dministration of their country. It was really a triumph r bureaucracy at the expense of national sentiment.

Departmental Unity.

Mr. JAMES STEWART said that, while he opposed the Bill, thought that the proposals of the Secretary of State for aving all the departments under one head would produce od results. If they took the health administration they ould find that in Edinburgh it was divided into three uildings in three different parts of the city. If the Govern- ent would introduce any proposals for providing the uildings which were clamantly necessary so that they uld have the Scottish departments under one roof there ould be whole-hearted support from the Labour Party r the Bill. It seemed to be suggested that there was fficulty in getting advice from the heads of the departments. is experience in office was a very brief one, but it taught m that it was easy to get into touch with the head of any partment. Suppose that it was a medical problem relating the health administration in any part of the country, and wanted advice. He applied to the head of the department r his experience and advice. His advice was freely tendered d as freely accepted. Such advice was very generally ted upon because one knew that there was ability and perience behind it. There was complete independence the part of the head of the department and on the part the person who had to supply the Minister with advice. rthermore they had the benefit every Friday morning of meeting of the Board of Health at which the heads of the rious departments were present. Either the Secretary or nder Secretary for Scotland took the chair and deliberated the problems for discussion. They had the benefit of all e experience of the members of the Board, and, finally, e Minister had to assume responsibility. He it was who me to a conclusion even if, as happened sometimes, the ole of the Board was against him. If his experience and at of the Secretary for Scotland had been similar, then the anges proposed in the Bill could not be beneficial. It was neficial also for local authorities to meet the Board of alth to discuss the health administration of the local bodies. r that very strong reason they ought not to depart from e Board of Health system and create new departments. ere had been for some time a movement for securing ity among local authorities. Economy and efficiency could developed in a way that was not possible under the sent system. In Lanark, for instance, there were two or ee authorities carrying on medical administration, each lous of its own province, each running its own hospitals, l all carrying on in a way that was not beneficial. Here Board of Health came in. With its officials it could meet members of those conflicting authorities and discuss tters with them. Various men were at the Ministers' ow to jog him and to advise him in his attempt to ng these people to a right understanding. By this Bill y were going to give that up and to put nothing in its ce.

Mr. D. GRAHAM said that they had no complaints against various Boards. He had met the Board of Health and l nothing but pleasant recollections of the meeting. He arded every member of the Board as well qualified. ey were always courteous and willing to hear anyone, l they always produced arguments for any decision they ve.

Reply to the Debate.

Mr. WATSON (Lord Advocate), replying to the debate, l that at present there was no first-class civil service ition open to a Scotsman in Scotland, but the Bill would ke that possible. In reply to Dr. Shiels, he said there uld be no doubt whatever that the men who were appointed uld have the same capacity for administration as the sting individual members of the Board in their particular artment. What was wanted was administrative know- ge, the power of taking a concentrated opinion as an ninistrator, of all the expert knowledge available. That s the vital thing, and that was one of the reasons why he l, quite frankly, that the Boards were not as efficient as epartment would be. At the beginning, and he hoped in cession, the existing members of the Board of Health uld remain in office. In form their appointment would be erent, but they would be retained and their expert wledge would be continuously available. There would be change in that aspect of the matter, and the Advisory ncils would carry on just as at present.

The motion for the rejection of the Bill was rejected by votes to 66, and the Bill was read a second time and mitted to a Standing Committee.

NATIONAL HEALTH INSURANCE BILL.

Mr. CHAMBERLAIN (Minister of Health), on Monday, March 5th, introduced into the House of Commons the National Health Insurance Bill, a measure to amend the National Health Insurance Act, 1924, and other enactments relating to health insurance. The Bill was read a first time.

The new measure incorporates many of the recommendations of the Royal Commission which carried out an exhaustive inquiry into the question of health insurance, and among its provisions the question of a more effective dental service for panel patients is dealt with.

HOUSE OF LORDS.

WEDNESDAY, FEB. 29TH.

SHORTAGE OF FACTORY INSPECTORS.

Viscount ASTOR asked whether it was proposed to increase the number of factory inspectors so that the inspections might be adequately carried out and unnecessary loss of life and health prevented. He said that there was a large number of places, rather over a quarter of a million, which were technically factories and workshops and liable to inspection. Of these about 129,600 were factories, as distinct from workshops. In order to carry on the inspection of these factories the whole staff consisted only of 205. From that number they had to deduct those organisers and technical advisers who did not carry out routine duties of inspection, so that there was only something like 170 to 180 men and women to carry out the inspection of over a quarter of a million premises. The duties of the inspector under the various Factories and Workshops Acts were multitudinous. There ought to be at least one inspection a year. There were certain premises where dangerous processes were carried on and where the atmosphere was apt to be vitiated, and these ought to be inspected about once every three months. It was obvious that a staff of 170 or 180, however zealous and hard-working, could not possibly get round so large a number of premises as a quarter of a million. In 1925 there were 27,663 factories, as distinct from workshops, which were never inspected at all. There were 1290 factories which were not inspected either in 1925 or 1926. That this state of affairs was unsatisfactory was proved by the fact that in 1926 there were 140.000 accidents, 800 of which were fatal. It was true that the number of fatal accidents in 1926 was slightly less than in the previous year, but that was very largely because in those industries where a large number of accidents occurred many firms were either working part-time or were closed down altogether. Actually, in the industries which were not stopped as the result of strikes, or from other causes, there was an increase of fatal accidents. He was informed on good authority that the staff of factory inspectors was about 25 per cent. below the figures fixed in 1921 as being desirable and necessary. The responsible Minister, speaking in the House of Commons, had admitted a shortage of inspectors, and year by year, when questioned about it, had said that the Government were waiting until the passing of the Factories Bill. He could not see why the Government were waiting for that Bill, more particularly as he regretted to see that year by year that very much-needed and oft-promised measure was repeatedly postponed. It was not sufficient to say that one or two more inspectors either had been or might be appointed. If it was true that there was anything like a shortage of 25 per cent., he hoped that they would be told that the Government contemplated appointing a sufficient number of inspectors so that those duties and responsibilities which were necessary, and which were intended by Parliament, might be properly carried out and that there might be adequate safeguards for health, limb, and life.

Home Office Reply.

Lord DESBOROUGH, speaking for the Home Office, said that the present position of factory inspection might be stated thus: In 1913 the staff numbered 222, which included 9 inspectors at headquarters; the establishment was now 206, including 20 at headquarters. In comparing these figures allowance had to be made for the transference of the factory inspection service in Ireland to the Free State Government and the Government of Northern Ireland, which involved a reduction of seven posts. This showed an actual reduction of strength of nine posts, which were given up in the interests of economy. The number of visits paid to factories and workshops had dropped, he was sorry to say, from 406,445 in 1913 to 300,368 in 1926. That decrease, however, related entirely to inspection of workshops—that was to say workshops where no power was employed. The number of visits to factories (which were the more important premises under the Acts) had not only been maintained, but had improved, the number of visits to factories in 1926 being 188,172, as compared with 176,591

in 1913. The present Government, and the previous Government, had been aware all along that the standard of inspection was too low, and that the inspectorate staff would have to be increased to secure the high standard and the enforcement of the law in factories and workshops which they would like to see attained. Moreover, if and when the Factories Bill, which was introduced in the House of Commons last year, became law, fresh burdens would be thrown on an already overworked staff. The policy of the Government, which, like their predecessors, had been to wait until that Bill had been passed and the whole question of the organisation and strength of the staff could be examined in the light of the new situation and duties created by the Bill, had been explained by the Home Secretary in the debate in the House of Commons in July, 1927. So far as the fire at the premises of the Waste Film Products, Ltd., was concerned, two questions arose: First, whether the Celluloid Regulations of 1921 made under the Factories and Workshops Act, 1901, which applied to all celluloid factories were sufficient to ensure the highest standard of safety in works where the waste products of film were dealt with. It had already been recognised that these general regulations were inadequate for that purpose. Secondly, whether this accident had revealed a need for the immediate appointment of nine inspectors in the metropolitan area where works of this nature seemed to have congregated. The Home Secretary was satisfied that the existing regulations were not sufficiently stringent. The film stripping industry was one of quite recent development, and was, in the opinion of the chief inspector of factories, appreciably more dangerous even than the film manufacturing industry. The Home Secretary therefore decided that two new codes of regulations should be issued, one dealing with the manufacture of the film and the other with works in which waste film was manipulated. Both these codes had now been made and came into force on March 1st. They introduced a number of new and important safeguards. At the same time the Home Secretary came to the conclusion that having regard in particular to the development of this industry in the metropolitan area, it was necessary to make some addition at once to the staff in the London divisions. He therefore obtained the sanction of the Treasury to appoint two additional men inspectors (included in the establishment of 206 already mentioned), and these appointments would be made as soon as possible. In the meantime, all waste film works had been specially visited by one of His Majesty's engineering inspectors of factories, and the steps necessary for compliance with the new regulations had already been taken in hand. He supposed that the new Factories Bill would be coming on next session, but in order to expedite matters the Home Secretary had already decided to advance the date of appointment of a committee to go into this question of additional inspectors so that no time should be wasted, although it would be very difficult, until they knew how the new Factories Bill was going to emerge, to draw up any regulations or to appoint many more inspectors. Nor could they claim that an increase of factory inspectors would obviate these accidents. Accidents occurred, unfortunately, in a great many places which were most carefully inspected, and he did not think that the inquiry which had been referred to satisfied the authorities that the deplorable accident was necessarily due to a lack of inspection, or would have been avoided had there been more inspectors.

Factory Inspectors and the Prevention of Accidents.

Lord ARNOLD said that the reply of Lord Desborough had done very little indeed to deal with this matter, and did not hold out any real hope of improvement. In his view, the number of factory inspectors ought to be doubled. The trouble in this matter was another instance of the indifference of the Government to labour interests. It was not economy to be cheeseparing in the matter of factory inspectors: it was parsimony of the worst description. If the Government had the will to deal with this matter they could do so perfectly well, without waiting for the Factories Bill.

Lord BANBURY OF SOUTHAM said that personally he regretted that Lord Desborough had not said that he was going to reduce the number of inspectors instead of increasing them. What they wanted was to give people an opportunity to work as long as they possibly could and not to hamper them by introducing all sorts of inspectors who cost money and did no good to anybody.

Earl RUSSELL said the insufficiency of factory inspection had been a growing scandal for many years. The solatium they were offered of two additional inspectors was really too ridiculous.

Lord JOICEY said he thought that there was a great deal of exaggeration with regard to the value of inspectors generally. He would welcome most heartily the appointment of more inspectors if he believed that they would reduce accidents, but he was very doubtful about it. If they consulted large employers they would find the opinion that strong pressure ought to be exercised on trade-unions to induce their members to make known to the employers or the foremen, all cases where negligence was shown in carrying out regulations. That would have far more effect in stopping accidents than the employment of more inspectors.

Lord PARMOOR said that he did not doubt that the employers had good intentions in this matter, but he repudiated the suggestion that the workmen were to blame rather than the employers. He put no blame on either party. In the history of factory work it had been found that adequate inspection was necessary in order that the lives and health of the workers might be properly protected. There was no dispute on that question, and it was beside the point to suggest special intentions or special wickedness on either side. They were admittedly in the position of having a shortage or insufficiency of inspectors at the present time, and that ought to be put right at the earliest moment, not in the interests of a class, but in the interest of industrial life as a whole.

DANGER OF LEAD TETRA-ETHYL IN MOTOR SPIRIT.

Lord BUCKMASTER moved:

"That it is expedient that His Majesty's Government should immediately set up a Committee to advise as to the public danger that may arise from the use of lead tetra-ethyl in motor spirit."

He said that last summer he was speaking to an eminent medical man, and he asked him if he knew anything about ethyl spirit. He (Lord Buckmaster) replied that he knew nothing at all. The medical man said that he would very soon know something about it if the spirit was introduced here. It was one of the most dangerous things, he said, that men could possibly handle. He (Lord Buckmaster) said in those circumstances the Home Office or the Ministry of Health would either prevent or make strict regulations for its use. He was sorry to find that his optimism in that respect had had no foundation in fact. The spirit had been introduced here, at the instance of one of the most powerful trade organisations in the world, and was being pressed for sale, and, so far as he knew, neither protection nor regulation from either the Home Office or the Ministry of Health had been provided with regard to its use. The spirit was discovered in 1859, but nothing was done with it until about 1879, when Prof. Franklin investigated it more closely. It was then classed as the most dangerous poison known. During the war it was considered as a proper poison gas, as it was a means by which they could disseminate more certain death than with any other poison. It was rejected, however, not because of any deficiency in its lethal power, but because its method of dissemination either through shell or liberation from tanks, rendered it unsuitable. The detonation destroyed some of its chemical molecules and so destroyed some of its effects. This spirit had two great values. The first was that owing to the fact that it permitted of greater compression than ordinary petrol vapours it enabled cars to take gradients more easily than the ordinary spirit, and it also avoided the knocking which was due to some detonation not quite fully explained which in car-running was regarded as most unpleasant. What was to be said on the other side? The spirit contained as its very essence lead tetra-ethyl, which distinguished it from the ordinary motor spirit. If that ingredient were either put upon the hand or breathed in a person ran a very grave risk indeed of lead poisoning, and as it was capable of being dissolved in oil and was highly volatile, there was no need for any abraised surface on the skin for the poison to take effect. Indeed, an eminent scientific man had said to him recently: "I would not have one drop of this on my finger. If I had, I would spend the whole of the rest of the day trying to secure cleanliness." Like so many of these things, the action of the spirit was not necessarily instantaneous. Its real mischief was a form of lead poisoning more deadly than the lead poisoning effected through the use of paint or of lead glazing. It was an illness which came on without warning. If pain was a sentinel to warn one of the approach of illness, then the sentry often slept at his post, for diseases like cancer, tuberculosis, and lead poisoning passed him unchallenged and entered into the very citadel of life. That was the character of this particular poisoning and unless some steps were taken the consequent danger which might result was very grave indeed to contemplate. The spirit had its origin in the United States, and hearing of the mischief it had caused, the Government of the United States appointed a commission some two years ago to inquire into the matter. The commission reported that no positive evidence could be obtained of harmful effects, but they urged strongly that suitable appropriation be requested from Congress for the continuance of the investigations. So far as he could see, even in America this substance was only allowed to be used subject to rules and regulations issued by an authority which was equivalent to the Ministry

[ealth here. Those rules and regulations were really ather laughable. For instance, it was prohibited carelessly o spill the spirit on the floor of a garage. Had their lordhips ever found a garage where there was not some petrol arelessly spilt on the floor? Again, they had to wash heir hands before food or tobacco or anything else was onveyed to the mouth. Those were some of the suggestions ade in America to protect people against the attack of n insidious and deadly disease, but they all knew that ch rules were perfectly useless here, and he did not suppose at they were going to entrust the safety of the British eople to recommendations made by the authorities in nother country. This country was bound, if warned, to ok after this matter. Had they been warned? Sir William ope, professor of chemistry at Cambridge, wrote a letter the *Times* of Feb. 22nd, in which, after quoting from this port, he said :—

"Pharmacological evidence has been published which proves nclusively that lead tetra-ethyl is absorbed from its dilute trol solutions by animals through the skin and by the lungs. garage hand who continually wets his skin with such a liquid, lashes it on his clothes, eats his food without scrupulous tention to cleanliness, or breathes an atmosphere tainted with e vapour, must thus be liable to contract lead poisoning; reless engine cleaners or repairers will incur a similar liability."

Prof. Baker, who was the President of the Chemical Society, Fellow of the Royal Society, professor of chemistry and vernor of the Imperial College of Science and Technology, rote another letter to the *Times*, to the following effect :—

"Sir William Pope has, I think, understated the case against e use of lead tetra-ethyl in motor spirit. This substance does ot act on the body as an ordinary lead poison, but it has a ecific action which is much more harmful. It is little less isonous than the corresponding mercury compound which used the death of two promising young chemists at Oxford any years ago. Lead tetra-ethyl passes rapidly through the in, is absorbed by the blood, and causes very severe nervous ouble. If sufficient is absorbed death occurs in a few weeks."

Prof. Baker also pointed out that whenever this spirit as put upon the skin it found its way into the body, even though the skin was unabraised. He concluded his letter ith a statement which required further comment. He id :—

"I wrote, as President of the Chemical Society, to the Ministry Health more than a month ago, calling their attention to the gency of the matter. So far as I know, nothing has been ne."

ot only had nothing, as far as he knew, been done, but is distinguished gentleman who was seeking to put his nowledge at the service of the Government received thing for his pains except a curt acknowledgment his letter. That was not the way in which a most ninent and distinguished scientific man should be treated a Government department. If the statements he had oted were doubted, then there ought to be a committee inquiry. Unless the Government acted nothing would done. These vast trade organisations did not care how any people suffered from the exploitation of their goods, r commerce had no conscience and trade no tenderness of art.

Lord GREENWAY supported the motion. He did so, he id, in the interests of the oil industry as a whole. It ight not be generally known that all the big petrol producing mpanies were engaged on the problem of how to produce e quality of natural or compounded spirit best qualified meet the demands of the large portion of the public o now favoured high compression engines in motor-cars, it none of them was desirous of producing a spirit which s liable to criticism on the score of danger. The position regarded tetra-ethyl spirit was that this new compound d been placed on the market, and while the company ich introduced it claimed that it was non-injurious to alth, various statements had appeared in the press ggesting that it was toxic in character and dangerous the health, or even the life, of the people who used or ndled it. The number of people who used or handled trol was now so enormous that it was essential in the blic interest that a properly constituted board, including me of our leading chemists and toxicologists, should be pointed definitely to settle once and for all the point in spute.

Reply for the Government.

The MARQUESS OF SALISBURY, Lord Privy Seal, replying the Government, said that he admitted that too long period had been allowed to elapse before the Ministry of ealth replied to Prof. Baker's letter of warning on this bject. If that eminent chemist felt in the least that he d not been properly treated, he hoped that he would cept from him (Lord Salisbury) the fullest apologies. regarded the substance of Lord Buckmaster's speech, he l not think that a very great deal of difference would be nd between the Government and the noble and learned d. So far as the Government were concerned, there s no indifference towards this matter, the importance of which they fully recognised. They recognised the risk attaching to this commodity and proposed to deal with it. Tetra-ethyl itself was highly dangerous and had, of course, very serious consequences if it was not properly treated. But that did not mean that it must not be manufactured. Many highly dangerous things were manufactured, such as vitriol and arsenic. But the greatest care ought to be taken. As a matter of fact, tetra-ethyl was not manufactured here, but in America. A moment of special risk occurred when, having been imported into this country, it was blended with petrol spirit. This blending process involved considerable risk and that was a matter which was receiving the attention of the Home Office at this moment. Up to now, however, no case of lead poisoning had arisen from this commodity in England. Turning to the petrol, which had a very small admixture of this commodity, Lord Salisbury said that he was correct in saying that it was a mixture of 1 in 1300 parts, or something of that kind. He did not say that that eliminated all its toxic character, but he wanted the House to have a true picture of the exact condition of affairs. The blend was undoubtedly a very useful commodity and a very useful source of power. The Government had to consider how far they ought to interfere with a recognised improvement in the source of power, especially for aeroplanes. The Public Health Department in the United States appointed an investigating body consisting of seven distinguished scientific men to inquire into the danger of ethyl petrol—the spirit which was slightly diluted with this commodity. That committee reported that no positive evidence could be obtained of harmful effects attributable to the use of ethyl gasolene. The first conclusion of the committee was :—

"Drivers of cars using ethyl gasolene as a fuel and in which the concentration of tetra-ethyl lead was not greater than 1 part to 1300 parts by volume of gasolene, showed no definite signs of having absorbed lead after exposures approximating two years."

The second conclusion was :—

"Employees of garages engaged in the handling and repairing of automobiles and employees of automobile service stations may show evidence of lead absorption. In garages and stations in which ethyl gasolene was used, the amount of apparent absorption was somewhat greater than in those without ethyl gasolene";

he would like Lord Buckmaster to note this limitation—

"but the effect was slight in comparison with that shown by workers in other industries when there was definite danger from lead . . . and for the periods of exposures studied was not sufficient to produce lead poisoning."

And this was the third conclusion :—

"In the regions in which ethyl gasolene has been used to the greatest extent as a motor fuel for a period of between two and three years, no definite cases have been discovered of recognisable lead poisoning or other disease resulting from the use of ethyl gasolene."

He did not desire their lordships to accept the conclusions of that Report as conclusive. After all, it was not a British Committee and he had no means of testing the competence of the scientific men who were said to have conducted the inquiry. But undoubtedly it was a body of scientific men appointed by the relevant Department in the United States. He would therefore suggest that they must approach the condemnation of this commodity with a certain amount of caution and not fall into the error of assuming the worst until it was proved. Undoubtedly the British Government could not be indifferent to the risk to which the noble and learned lord now called attention, and they were about to undertake research of a careful character. For that purpose the Government were going to appoint an Inter-Departmental Committee, the composition of which had not been definitely settled, but he thought that it would consist of representatives of the Ministry of Health, the Home Office, and the Medical Research Council. This committee would be appointed forthwith.

Scientific Investigation.

Earl RUSSELL said that he was very glad that this Committee was going to be set up. They knew, of course, *prima facie* that lead poisoning was a most insidious and deadly disease, and if this material actually caused poisoning of that nature there would be the gravest necessity to take action.

Lord BUCKMASTER said that Lord Russell seemed satisfied. He wished he could be. An Inter-Departmental Committee was not what he wanted. What he desired was a scientific investigation, not an investigation by a Departmental Committee. Departments did not have eminent scientific men on their staffs.

The Marquess of SALISBURY: The Medical Research Council has.

Lord BUCKMASTER said that the Medical Research Council had a certain number of doctors, but what they wanted were scientific men, such as eminent chemists, who knew about

this matter and would satisfy Lord Salisbury who spoke lightly of one in 1300 that watered vapour from nickel would poison with one in 20,000. Prof. Baker had written to him a letter in which he said that after this spirit had burned in the cylinders of the engine the lead came into the exhaust as a fine quality of lead oxide and that in a crowded street, like Piccadilly for example, the unfortunate passer-by would be exposed to the same danger of lead poisoning as painters were before they were protected by Government action. It was not a matter of small moment because people were only found to be slightly affected. They would go on getting more and more affected till illness and death overtook them and they would have done nothing except to wait nine months and then set up an Inter-Departmental Committee. But he knew that it was no use asking for more. If the House was divided and they beat the Government it would have no effect. Therefore, having done his duty by calling attention to the matter, he did not propose to proceed with his motion.

The Marquess of SALISBURY said that if Lord Buckmaster thought that there should be scientific men added to those who sat on the Inter-Departmental Committee he would represent that view in the proper quarter.

The motion was, by leave, withdrawn.

TUESDAY, MARCH 6TH.

DESTRUCTION OF VERMIN BILL.

Lord STRATHSPEY introduced the Public Health (Destruction of Vermin) Bill which was read a first time.

HOUSE OF COMMONS.

TUESDAY, FEB. 28TH.

Post-office Messengers and Flat-foot.

Mr. AMMON asked the Postmaster-General whether all applicants for service in the Post-office as messengers suffering from flat-foot were medically rejected; and whether the number so rejected could be given.—Sir W. MITCHELL-THOMSON replied: It is the practice to reject all applicants for service in the Post-office as boy messenger who are found to be suffering from flat-foot. The number so rejected during the year 1927 was 17.

Night Work by Youths in Mines.

Mr. LEE asked the Secretary for Mines whether he was aware that many of the 28,000 youths of the ages between 14 and 16 working underground at the collieries in the country were expected to work on the night shift; that youths of a similar age were not allowed by law to work on the surface at night; whether any of these youths were medically examined as to their physical fitness for working underground; and whether he was prepared to recommend that facilities be granted for placing youths working underground on the same basis as youths on the surface.—Commodore H. DOUGLAS KING replied: I am aware of the facts referred to in the first two parts of the question. As regards the third part, medical examination is the practice at some collieries, but it is not compulsory by law. In reply to the last part of the question I would remind the hon. Member that in 1911, when Parliament passed the Coal Mines Act of that year, it was decided that the prohibition against night work by boys on the surface should not be extended to underground work, and that this decision was confirmed by the Washington Convention of 1919 and by the Employment of Women, Young Persons and Children Act of 1920. I am not at present aware of any sufficient reason for reversing this decision.

WEDNESDAY, FEB. 29TH.

Tetra-ethyl Poisoning.

Lieut.-Commander KENWORTHY asked the Minister of Health whether he will state the steps, if any, he proposes to take to prevent injury to workmen, persons employed in garages, and the general public from ill-effects from the use of petrol diluted with lead tetra-ethyl; if he was aware that lead tetra-ethyl was a poisonous substance easily absorbed by the blood through the skin and that its use in garages had been proved to be dangerous; and whether, until his department has examined into this matter, he will consider issuing special warnings to garages and to the local authorities.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: Lead tetra-ethyl is a poisonous substance, and those who make or sell preparations of petrol which contain it should take or advise precautions designed to avoid danger from handling or using these products. There is at present no definite evidence of injurious results following the use of ethyl spirit. The desirability of further inquiries or research into the nature of any danger to the public from its use is being considered in conjunction with the Medical Research Council, but pending such inquiry it is not proposed to take action on the lines suggested by the hon. and gallan Member.

Lieut.-Commander KENWORTHY asked if the righ hon. gentleman had seen a letter in the *Times* recentl from the holder of one of the Chairs of Chemistry at Can bridge in which he said that even the flooding of a carburette and getting this petrol on the skin might bring about ver serious poisoning, and in view of this would the right ho gentleman issue a warning interim to the report of th investigations;

Dr. VERNON DAVIES: Is the right hon. gentleman awar that Switzerland prohibited this ethyl petrol by ordinanc in 1925?

Sir KINGSLEY WOOD: No, Sir.

Persons Found Dead in London.

Mr. DAY asked the Home Secretary the number of perso who were found dead, and the number who remain unident fied, in the Metropolitan police area for the last 12 montl to the last convenient date.—Sir WILLIAM JOYNSON-HICK replied: In 1927, 707 dead bodies were found in the Metr politan Police District; 77 bodies of newly born infants, ar 74 other bodies remain unidentified.

Municipal Water-supplies.

Sir ROBERT THOMAS asked the Minister of Health whethe in view of the increasing competition among municip authorities for water-supply sources, he would consid making a Government allotment of water-bearing are in order to prevent small authorities from being squeez out by large wealthy cities.—Sir KINGSLEY WOOD replie The interests of small authorities are carefully watched ov by my Department when examining proposals for wat supplies and, where necessary, reports are made to Parli ment. A general survey and allotment of water-bearin areas would entail considerable expense and delay, and n right hon. friend prefers the system which has been adopt of appointing Regional Water Committees who estima local needs and then proceed to formulate definite propos for supplying them.

Milk Production.

Mr. GRIFFITHS asked the Minister of Agriculture t quantity of milk produced and available for consumption 1923, 1924, 1925, 1926, and 1927, and the quantity approximate percentage that was surplus to normal requi ments during those years.—Mr. GUINNESS replied: T following is the information asked for: The estimat production of milk (exclusive of milk fed to calves and pi per million gallons, in England and Wales in the und mentioned years, from June 1st to May 31st, was as follow 1923–24, 1100; 1924–25, 1117; 1925–26, 1135; 1926–2 1150. As a result of the special inquiries made in connexi with the last Census of Production it was estimated that t amount consumed as liquid milk in 1924–25 was abo 765 million gallons. With regard to the latter part of t question Mr. Guinness regretted that he had no informatio

Deaths from Small-pox.

Mr. GROVES asked the Minister of Health the number deaths from small-pox in England and Wales for ea quarter of the past year.—Mr. N. CHAMBERLAIN replie The following provisional figures for England and Wales 1927 give the deaths in respect of which "small-po appeared on the medical certificates as the cause, or one the causes, of death:—

Quarter ended March 31st	.. .. ..	19
,, June 30th	.. .. ..	17
,, Sept. 30th	.. .. ..	7
,, Dec. 31st	.. .. ..	6
		49

THURSDAY, MARCH 1ST.

Pensions Hospitals in Scotland.

Dr. SHIELS asked the Minister of Pensions: (1) If it w his intention to close Bellahouston and Craigleith Hospita and, if so, were the patients to be sent to Edenhall. Whether he proposed to return all Scottish disabled m in English hospitals to Scotland for treatment near th own relatives and friends. (3) How many hospital be the Ministry was to maintain in Scotland; and would th beds be in one hospital or in more than one.—Ma TRYON replied: Arrangements have been made, as I ha already informed the House, to close Craigleith Hospit the return of which has been asked for by the Parish Coun at an early date. The patients remaining in that institut who are occupying less than one-fifth of the availa accommodation, will be removed to Edenhall, which has be placed at the disposal of the Government by the Scott Red Cross and is being fully equipped as a modern surgi and medical hospital. The closure of Bellahouston Hospi is not at present in contemplation. I am anxious to exte the Ministry's tenure of this hospital and, as I have alre informed the hospital, I am in communication with

lasgow Corporation with that object and I am in hopes that satisfactory agreement will be reached. It is not possible estimate at the present time what will be the final requirements of the Ministry in Scotland in respect of special ospital accommodation of its own, but it is my intention ow, as heretofore, to provide such accommodation of the st quality that can be obtained for as long as it may be quired. The only cases having Scottish domicile who are ceiving in-patient treatment in England are cases suffering om certain special disabilities, such as diabetes and certain pes of neurasthenia, for which treatment is now provided the Ministry in a limited number of centres. It is not oposed to alter these arrangements, which are in the terest of the pensioners and have worked satisfactory some years past.

Panel Practitioners and Certification.

Mr. MALONE asked the Minister of Health what evidence had to show that laxness in certification by panel doctors counts for the increase of over 11 per cent. in the amount id in sickness and disablement benefits in 1927; whether had any information regarding the increase in sickness ims in various parts of the country, such as the coalfields d other depressed areas; and what were the further asures with regard to certification which he proposed adopt?—Mr. CHAMBERLAIN replied: The hon. Member pears to be under a misapprehension. I have never ggested that the whole of the increase in the sickness and ablement benefits in 1927 as compared with 1926 is ributable to laxity in certification. But for the evidence at some want of care in certification is a factor in the rease, I would refer to the speech of Sir Kingsley Wood the debate on Feb. 20th. It is not practicable to ascertain precise amount of the claims in any particular area, t such evidence as is obtainable indicates that the increase general and is not limited to particular districts. The ole question of certification is now being examined in nsultation with the Insurance Acts Committee of the itish Medical Association.

Danger of Tetra-ethyl Spirit.

Colonel HOWARD-BURY asked the Home Secretary ether his attention had been drawn to the use of a new tor spirit called ethyl; and whether he had held or would d an official examination into the nature of this motor rit in view of the dangers of lead posioning that might ur from its use.—Mr. CHAMBERLAIN (Minister of Health) lied: As announced by my noble friend, the Lord Privy al yesterday, I propose to set up a Committee of Inquiry, which the Home Office, Air Ministry, the Medical search Council, and the Ministry of Health will be represented, and which will also include the Government chemist some men of science unconnected with any department. e exact composition and terms of reference of the Comtee have not yet been decided.

MONDAY, MARCH 5TH.

Medical and Sanitary Service in Kenya.

Mr. BARR asked the Secretary of State for the Colonies ether his attention had been called to the fact that it had ently been laid down by the Deputy-Director of Sanitary vice in Kenya that the minimum for a large rural native trict, containing 100,000 to 200,000 people, was one trict medical officer, one medical officer of health, one pensary medical officer, two European nursing sisters, European sanitary inspector, and possibly a European pital assistant and a storekeeper, and, in addition, an quately trained native subordinate staff, a hospital with ommodation for about 100 patients, and from 6 to 12 -dispensaries; whether this standard was in force in of His Majesty's Colonies; and whether pressure was ught to bear on the Governments to increase their dical staffs up to this standard.—Mr. AMERY replied: attention has been drawn to the interesting address to Royal Society of Tropical Medicine and Hygiene in ch this statement occurred. So far as I am aware the ndard suggested has not been endorsed by any Colonial vernment, and as the medical requirements of the Colonies ler so greatly it would be impracticable to regard such a gestion as a general standard of administration. Oversea vernments are everywhere endeavouring to maintain a dical staff adequate to their requirements and I am glad say that in some of the African territories a relatively h standard has already been achieved.

Factory Inspection in Iraq.

Sir ROBERT THOMAS asked the Secretary of State for the onies whether there was any inspection of the factories raq where dates were packed for export to this country; , if not, whether, in view of the danger of disease being oduced by this means, he would inquire into the conons of cleanliness under which this industry was carried —Mr. AMERY replied: Stringent measures were taken the Iraq health authorities during the cholera epidemic of last year to ensure that all dates exported from Iraq were free from any possibility of infection. I am not aware whether under normal conditions the Iraq Government require inspection or consider it necessary. I am, however, asking the High Commissioner for a report on the subject. I am advised that there is no evidence of disease being introduced into this country through the medium of Iraq dates.

Medical Examination of Canadian Emigrants.

Mr. BENJAMIN SMITH asked the Secretary of State for Dominion Affairs whether, as Canadian medical officers had been detailed for duty in this country for the purpose of examining and certifying intending emigrants, emigrants so approved were secured against rejection after embarkation; and whether his department was furnished with statistics of the number of persons accepted or rejected by these officers.—Mr. AMERY replied: Intending settlers in Canada who are examined and passed by Canadian medical officers are not required to undergo further examination and are not liable to rejection on medical grounds on arrival at the port of entry unless essential information has been withheld, or unless some disease has developed in the interval. The new arrangements only came into operation on Feb. 14th and no information is as yet available as to the numbers of applicants accepted or rejected by these officers.

Isolation of Pauper Small-pox Contacts.

Mr. CHARLES EDWARDS asked the Minister of Health whether he had received a letter from the Bedwellty Council asking that the law should be amended so as to provide that in the case of persons who had been in contact with, or were suffering from, small-pox or other infectious disease in casual wards of poor-law institutions, the medical officer of health should be empowered to have them detained and isolated for such period as he might deem necessary; and would he take steps to ensure this being done.—Sir KINGSLEY WOOD replied: The reply to the first part of the question is in the affirmative. As regards the second part, there is power under the present law to secure the removal to hospital of any person who is suffering from a dangerous infectious disease and is without proper lodging or accommodation, but as at present advised, my right hon. friend does not think it necessary to introduce legislation conferring similar powers in regard to persons who have been in contact with cases of such diseases, though not themselves so suffering.

Naval Hospitals.

Dr. VERNON DAVIES asked the First Lord of the Admiralty if he could give a full list of naval hospitals at home and abroad; the number of beds in each hospital: and the number of personnel attached to each hospital.—Lieut.-Colonel HEADLAM (Parliamentary Secretary to the Admiralty) replied: The particulars asked for are as follows:—

Royal naval hospitals at—	Beds available.	Salaried staff.	Wages staff.	Total of staff.
Haslar	625	62	334	396
Plymouth	590	52	272	324
Chatham	490	55	279	334
Portland	104	12	37	49
South Queensferry ..	103	8	29	37
Great Yarmouth ..	213	4	38	42
Malta	365	31	131	162
Cape of Good Hope ..	48	5	21	26
Bermuda	77	6	16	22
Hong-Kong	107	11	70	81

TUESDAY, MARCH 6TH.

Closing of Military Hospitals.

Dr. VERNON DAVIES asked the Secretary of State for War how many beds had been reduced by the closing of the military hospital, Chatham, the Alexandra military hospital at Cosham, and the military hospital at Devonport, respectively; what economies had been effected by this reduction; and what reduction in hospital personnel had followed the closing of these hospitals.—Mr. DUFF COOPER (Financial Secretary to the War Office) replied: So far as the War Department is concerned the answer to the first and last parts of the question is that there has been a net reduction of 215 equipped beds and of 15 officers, 15 nurses of the Queen Alexandra's Imperial Military Nursing Service, and 149 other staff. As regards the second part of the question, in addition to economies in beds and staff, the buildings have been set free for other Government purposes or ultimate disposal.

Methylated Spirit Drinking in Scotland.

Mr. BARR asked the Secretary of State for Scotland how many arrests for drunkenness, alleged to be due to the drinking of methylated spirits, were made by the police in

the city of Glasgow during the 12 months ending Oct. 31st, 1927; and the number of such arrests in each of the wards of the city where they took place or, alternatively, the numbers in each of the respective police divisions of the city.—Sir J. GILMOUR replied: The following return shows the number of persons apprehended for being drunk and incapable in the various police divisions of the city of Glasgow, during the year ended Oct. 31st, 1927, whose condition is believed to have been due to the drinking of methylated spirits:—

Division.	Males.	Females.	Total.
Central	63	52	115
Western	86	31	117
Eastern	23	7	30
Southern ..	59	20	79
Northern.. ..	26	8	34
St. Rollox ..	6	3	9
Queen's Park ..	4	—	4
Maryhill	1	—	1
Govan	4	3	7
Partick	7	2	9
Marine	24	6	30
Total ..	303	132	435

Skimmed Milk and Rickets.

Mr. EVERARD asked the Minister of Health whether he had received any reports that the prevalence of rickets among children in some districts was largely caused by the fact that they were being fed on imported skimmed milk which was marked unfit for babies; and whether he would take steps to prevent the use of this commodity as a food for infants.—Mr. CHAMBERLAIN replied: I have seen a newspaper report of a statement of a lecturer on agricultural economics to this effect. I am advised that the feeding of infants on skimmed milk in any form would tend to produce rickets, and it is for this reason that I have made regulations requiring the words "Unfit for babies" to be displayed on the tins. Recently I have issued fresh regulations which will have the effect of displaying these words more prominently.

Mr. EVERARD asked whether in the public interest the right hon. gentleman would publish figures showing the value of English milk as compared with this foreign condensed milk as a clean product?

Mr. CHAMBERLAIN: I do not think it is necessary to publish figures showing the difference between skimmed milk and full milk.

Mr. HARDIE: Is the right hon. gentleman not aware that the people who buy this skimmed milk have no choice, and does he still adhere to the view he gave in answer to a question as to the effect of skimmed milk on rickets?

Mr. CHAMBERLAIN: That does not arise out of the question, but I think the hon. Member has misinterpreted what I said.

Mr. KIRKWOOD: Does the right hon. gentleman not think that it is a libel upon our civilisation that mothers should have to buy this skimmed milk because they cannot afford to buy other milk to feed their babies?

Dr. VERNON DAVIES: Is the right hon. gentleman aware that a lot of this skimmed milk is sold in such small packages that people will buy it whether it is marked "Unfit for babies" or not; and will the right hon. gentleman not issue regulations to provide that this milk shall be sold in very much larger containers?

Mr. CHAMBERLAIN: I must have notice of that question.

Mr. REMER: Is the right hon. gentleman not aware of the growing importation of this skimmed milk and will he not look further into the matter to see whether some other steps cannot be taken to avoid this increased consumption which must be bad for the people who consume it?

Mr. CHAMBERLAIN: I cannot accept that statement. The hon. gentleman seems to consider that children and adults are in the same position. My advice is that though skimmed milk is very bad for infants it may be quite wholesome for adults.

Colonel HOWARD-BURY: Cannot the right hon. gentleman prohibit its sale for infants?

Mr. CHAMBERLAIN: I would do so if I was sure that the prohibition would be adhered to.

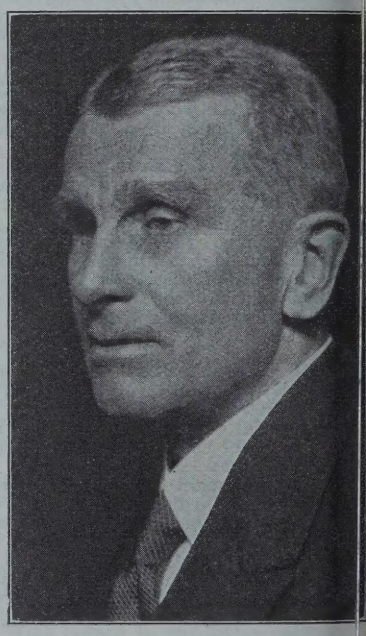
BEGGING LETTERS.—The chief constable of Cardiff informs us that medical men in various parts of the country are receiving begging letters from a person using the name of Jean N. Atherton, whose address is given as 10, Brook-street, Riverside, Cardiff. In a letter which has been forwarded for our inspection the writer requests that a loan should be sent in order to rescue her father from temporary difficulties, represents the family as being in great distress. We are informed that the writer of these letters has been convicted of obtaining charitable contributions by false pretences.

Obituary.

JAMES WHEATLEY, M.D. LOND., D.P.H.

WE regret to announce the death last Saturday Dr. James Wheatley, medical officer of health for t county of Shropshire. His health had failed for so months and he was unable to attend the ann dinner of the Medical Officers of Health, of which was this year president. His loss will be felt beyond the bounds of the public health service, his views on hygienic problems were widely c ceived and had attracted considerable attention.

Dr. Wheatley was educated at King's Colle London, where he held a Clothworkers' exhibiti He qualified in 1886, a year later taking his Lond degree with honours in medicine, his M.D. in 1890, and finally the diploma in public health of the Edinburgh Royal Colleges. After holding house appointments at King's College Hospital and demonstrating anatomy in the College, he went to Blackburn as house surgeon to the Infirmary, and remained there to become superintendent of the fever hospital, police surgeon, and finally medical officer of health. At Blackburn he made a careful study of hygienic conditions in the cotton industry, but it was not long before the offic county medical officer for Shropshire fell vacant, and began in 1901 what proved to be his life work. In ev department of county health work Wheatley m his impression, his name being especially associa with the problems of dental disease, of school hygie and of infant mortality. For many years he collec data regarding the incidence of dental caries in county, and in 1920 he published the result of examination of nearly 50,000 children, comparing condition of their teeth before and after the perio the Great War. While before the war only 5 per c of the under-fives were free from caries, no than 44 per cent. of post-war children showed dental decay, and Wheatley vehemently attribu this improvement to the restriction and modificat of food which occurred during the war, especia as it affected the supply of sugar, bread, and m The consumption of sweets, of highly refined flo and of crustless bread he regarded as the chief ca of dental caries, and he inaugurated a campa on these lines to combat deterioration in the teeth the nation. In regard to infant mortality, altho he admitted as factors in its reduction the scheme child welfare and antenatal care, he satisfied him that the chief effect was brought about by the op tion of the Education Act of 1870 in raising intelligence of the people and the sense of responsibi in parents. So long as education kept ahead material advancement he forecasted continu improvement in the health of mothers and yo



DR. JAMES WHEATLEY.

ildren. His views on public health as a whole ere set out with vigour and eloquence in an inaugural dress last October to the Society of Medical Officers Health. Put in a sentence Wheatley's message was at we cannot afford to interfere with the healthy d vigorous development of body and mind of a ge proportion of the people in order to prevent a w accidents—a new and stimulating conception of lative values in public health work. He refused accept as relevant the outlook of that part of the edical profession whose experience is entirely with k and abnormal persons. The lasting value of edical work must be judged by the improvement in e living of the ordinary individual. In his assessment health factors, Wheatley put in the first place search in its widest sense. He was keenly alive to e enormous benefit to medical practice arising t of modern physiological research, and desired inquiry into the causes of the fall in the death-e from tuberculosis during recent years. This ellectual detachment did not, it may be remarked passing, prevent him taking a large part in founding ounty sanatorium. But only second in importance research he placed the education of the people, ich he felt should be accelerated and made more ective by a vastly improved system of health visitors d district nurses to give instruction in the homes. One of his colleagues in the health service writes: Any profession or calling would be the poorer for loss of a man of Wheatley's type. He was never und by convention or tradition, and his philosophic nd had a refreshing way of throwing new light on problems. While he spoke out his thoughts rlessly, he was tolerant of the views of others, and owed himself a courageous and generous disputant. s kindly personality will be long missed, for he bodied more than most people the characteristics d down in the fifteenth Psalm."

Medical News.

THAMES FLOODS.—On Jan. 16th a conference was d at the Ministry of Health to investigate the flood aster of Jan. 6th and 7th (see THE LANCET, Jan. 21st, 142). The committee then appointed has now issued its ort and recommends that the statutory duty of inspecting d defence works within the county of London should nitely be placed with the County Council. In order to n the public in case of danger it is suggested that an ouncement should be made by the Meteorological Office, r consultation with the Port of London Authorities, n high tides may be expected; that a special watch uld be kept at Southend, warning to be given to the ropriate authorities when the tide reaches a specified t; and that a watch should be kept at selected points, lic notice being given in the locality if the water reaches danger level. The Committee also recommends that slative power should be obtained by the L.C.C. to prohibit erection of new dwellings, or the re-erection of old llings, on land within flood limits, unless their floors up to a specified level; but it recognises that the use of ement rooms for sleeping quarters can only be satisfac-ly dealt with as part of a general housing programme. ere basements do not now comply with the statutory irements, it is recommended that steps should be taken he earliest opportunity to prevent their being used as llings. The Committee has also come to the conclusion the L.C.C. should consider whether special protection uld not be afforded where there is likely to be damage of nusual kind—e.g., from creosote or mineral oil contained anks and barrels near the river.

Dr. W. J. Howarth, who has been medical officer of th for the City of London since 1913, has resigned his tion owing to ill-health. Dr. W. M. Willoughby will tinue to act until a successor has been appointed.

CENTENARY OF THE ROYAL FREE HOSPITAL.—siding at the 100th annual meeting of this hospital, d Riddell announced that the governors intended to brate its centenary by raising £100,000 for the endow-t of the dental clinic which is being provided and equipped Mr. George Eastman, of New York, and a further £210,000 building developments. The building will include "The en Mary Wing," a new maternity department, an nded pathological department, and new kitchens.

BELGRAVE HOSPITAL FOR CHILDREN.—Miss Barwell, matron of this institution at Clapham, is retiring after 29 years' service. In that period the accommodation has increased from 14 to 79 beds.

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held at the Municipal Buildings, Taunton, on Saturday, March 24th, at 10.30 A.M., when discussions will take place on Present Tendencies Regarding Disinfection and on House Refuse Collection.

HARVEIAN SOCIETY.—A clinical meeting of this society was held at the Royal Waterloo Hospital on Feb. 16th, Dr. Herbert French, the President, in the chair. Seven cases were shown by members of the staff of the hospital and two cases by Dr. G. de B. Turtle and Dr. R. Cove-Smith.

PHARMACEUTICAL SOCIETY OF GREAT BRITAIN.—A meeting will be held on Tuesday, March 13th, at 8 P.M., in the Lecture Theatre of the Society's House, 17, Bloomsbury-square, London, W.C., when Dr. H. H. Dale will give an address on Some Reactions of Pharmacology on Pharmacy.

ADRIAN STOKES MEMORIAL FUND.—It is announced that the Rockefeller Foundation has contributed £2000 to each of the two funds being raised at Guy's Hospital and at Trinity College, Dublin, in memory of the late Prof. Adrian Stokes.

UNIVERSITY OF LONDON MEDICAL GRADUATES' SOCIETY.—The first general meeting of this society will be held on Monday, March 12th, at 5 P.M., at the Rooms of the Medical Society of London, 11, Chandos-st., Cavendish-sq., W. The draft constitution and by-laws will be considered.

PROGRESS OF CONTRIBUTORY SCHEMES.—Since the Birmingham Contributory Scheme came into operation on New Year's Day, nearly 1000 firms have joined it, and nearly a quarter of a million workmen have been enrolled.—Some 700 business concerns are now coöperating with the recently established Liverpool Penny-in-the-Pound Fund, and 67,000 people are entitled to treatment.

AN EXHIBITION FOR A HOSPITAL.—Sir Philip Sassoon, hon. treasurer of the Royal Northern Hospital, has this week thrown open his house in Park-lane for a remarkable exhibition in aid of the funds of the institution. Many of the exhibits, which included examples of early English, French, and Italian needlework, furniture, and curiosities had never before been publicly shown. Treasures were lent from such famous houses as Knole, Arundel Castle, and Hardwicke Hall. Among them were the mitre and gloves of William of Wykeham, the coronation gloves of Edward VI., and the vest worn by Mary Queen of Scots at her execution.

DONATIONS AND BEQUESTS.—Mrs. Annie Louise Normandy, Anerley, London, S.E., left £3000 for charities, including £500 to the South-Eastern Hospital for Children, £300 each to the Royal Blind Pensions' Society, the National Society for Epileptics, Vauxhall Bridge-road, and £200 to Norwood Cottage Hospital, the British Home and Hospital for Incurables, King Edward's Hospital Fund, and the Earlswood Institution.—Lady Hudson, G.B.E., has given £3000 to the Westminster Hospital for the perpetual endowment of a ward in memory of the late Sir Robert Arundell Hudson, G.B.E., treasurer of the hospital from 1921 to 1927.

VICTORIA HOSPITAL, CAIRO.—The British Red Cross Society and the Grand Priory of the Order of St. John of Jerusalem have presented a clinic to this hospital, and last week it was opened by Lord Lloyd, British High Commissioner for Egypt. The hospital was founded in 1881 to provide treatment for the British, American, German, and Swiss communities, as well as Egyptians. Lord Lloyd at the same time unveiled in the hall of the hospital a tablet erected by British Freemasons in memory of the late Sirdar, Sir Lee Stack, who, at the time of his assassination, was District Grand Master of Egypt and the Sudan.

THE LATE DR. RAGLAN THOMAS.—The death is reported from Exeter of Dr. John Raglan Thomas, on Feb. 29th, at the age of 72. The son of a Llanelly doctor, he was educated at Epsom College, and entered St. Bartholomew's Hospital with a Gilchrist Scholarship, qualifying M.R.C.S. in 1876. He later graduated as M.B. Lond., with honours in midwifery and proceeded to the M.D. degree in 1887. After house appointments at St. Bartholomew's he succeeded to his father's practice and carried it on for ten years, being appointed medical officer of health for the Llanelly rural district. In 1888, however, he moved to Exeter where he became certifying factory surgeon, Admiralty surgeon, and medical referee under the Workmen's Compensation Acts. Dr. Thomas had many non-medical interests, and was a good shot, being for many years associated with the Volunteers. In 1908 he was Assistant Director of Medical Services for the Wessex Division of the Territorials, from which he retired with the rank of colonel in 1912, being appointed hon. physician to the King. He leaves a widow with two sons and five daughters.

Medical Diary.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.
MONDAY, March 12th.—5 P.M., WAR. Paper: Lieut.-Colonel Ernest Cowell, R.A.M.C. (T.A.): The Pathology and Treatment of Traumatic Wound Shock.
TUESDAY.—5 P.M., THERAPEUTICS. Papers: Dr. G. J. Langley: Clinical Assay of Digitalis. Dr. E. A. Carmichael: Stramonium in the Treatment of Post-Encephalitic Parkinsonism. 8.30 P.M., TROPICAL, PSYCHIATRY, NEUROLOGY, BALNEOLOGY. Special Discussion on Neuroses in the Tropics. Openers: Lieut.-Colonel O. A. R. Berkeley-Hill, I.M.S., Dr. H. S. Stannus.
WEDNESDAY.—5.30 P.M., SURGERY: SUB-SECTION OF PROCTOLOGY. (Cases and pathological specimens at 5 P.M.) Short Papers, &c.: Mr. Cuthbert Dukes: Demonstration of the Pathology of Obstruction Due to Tumours of the Bowel. Mr. W. B. Gabriel: Intestinal Obstruction Following Colostomy. Dr. Arthur F. Hurst: The Recognition, Cause, and Treatment of Megacolon in Adults. Sir Charles Gordon-Watson: A Method of Removing Adenomata of the Sigmoid Through the Rectum.
THURSDAY.—5 P.M., DERMATOLOGY. (Cases at 4 P.M.) Cases: Dr. W. J. O'Donovan: Chronic Exfoliative Dermatitis with Universal Melanodermia and Blood Changes. Other cases will be shown.
FRIDAY.—8.30 P.M., ELECTRO-THERAPEUTICS. Communication: Mr. A. E. Hayward Pinch: The Present Position of Radium Therapy. A discussion will follow.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.
The meeting of the Society of Medical Officers of Health for a discussion on the Control of Small-pox, fixed for March 16th, is postponed until a date to be announced after publication of the report of the Departmental Committee on Vaccination.

ROYAL SOCIETY OF TROPICAL MEDICINE AND HYGIENE.
THURSDAY, March 15th.—8.15 P.M. (at the Royal Army Medical College, Millbank), Demonstrations by Dr. E. Hindle, Lieut.-Colonel Clayton Lane, Lieut.-Colonel W. P. MacArthur, Dr. Alan McKenzie, Dr. A. C. Stevenson, Dr. J. Gordon Thomson, Prof. Warrington Yorke, Dr. U. Owen, and Lieut.-Colonel A. C. H. Gray.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, W.
MONDAY, March 12th.—8.30 P.M., Discussion on the Carrier Problem, to be introduced by Dr. J. E. McCartney, followed by Dr. John Freeman.

LONDON CLINICAL SOCIETY.
THURSDAY, March 15th.—8.30 P.M. (at the London Temperance Hospital), Clinical Evening.

EUGENICS SOCIETY.
WEDNESDAY, March 14th.—8.30 P.M. (at the Rooms of the Royal Society, Burlington House), Dr. W. R. K. Watson: Brixton Mental Tests.

BIOCHEMICAL SOCIETY.
FRIDAY, March 16th.—4.30 P.M. (at University College, Gower-street, W.C.), Annual General Meeting: Communications.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.
TUESDAY, March 13th.—5 P.M., Dr. Izod Bennett: Some Problems of Nephritis. Goulstonian Lecture (1).
THURSDAY.—5 P.M., Goulstonian Lecture (2).

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn-fields, W.C.
FRIDAY, March 16th.—5 P.M., Prof. Sir Arthur Keith: Variations and Anomalies of the Cervical and Costal Series of the Vertebral Column and their Application in Diagnosis and Treatment. Demonstration of Specimens.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith.
MONDAY, March 12th.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Dr. Trevor Davies: Gynæcological Department.
TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose, and Ear Department. 4.30 P.M., Dr. Shaw (Special Lecture): Abdominal Pain.
WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.
THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 3 P.M., Sir Henry Simson: Gynæcological Ward.
FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Ironside: Clinical Demonstration. 4.30 P.M., Mr. Vlasto (Special Lecture): Clinical Examination of Labyrinthine Diseases.
SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.
Daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments. Anæsthetic and Operative Surgery Classes.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION
St. James's Hospital, Ouseley-road, Balham, S.W.
WEDNESDAY, March 14th.—4 P.M., Mr. Norman Lake: The Surgical Dyspepsias.

NORTH-EAST LONDON POST-GRADUATE COLLEGE
Prince of Wales's General Hospital, Tottenham.
MONDAY, March 12th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.
TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.
WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.
THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M. Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.
FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children Diseases Clinics. Operations.
On Wednesday and Friday, at 2.30 P.M., there will also be demonstrations of Skin and Medical (Children) Cases by Dr. W. Jenkins Oliver and Dr. C. E. Sunderland respectively.
On Tuesday and Thursday there will also be demonstrations of Surgical Cases and Cases for X ray by Mr. W. H. Tanner and Dr. A. C. Dixon respectively.

NATIONAL HOSPITAL, Queen-square, Bloomsbury.
MONDAY, March 12th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: Epileptic Variants.
TUESDAY.—2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Disorders of Sensation.
THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Bailey: Electrical Testing of Muscles (in Out-patient Department).
FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Sir Percy Sargent: Cervical Ribs.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.
THURSDAY, March 15th.—4 P.M., Dr. W. G. Wyllie: Nephritis in Children.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.
WEDNESDAY, March 14th.—4 P.M., Consultations.
FRIDAY.—4 P.M., Mr. Gill-Carey: Focal Sepsis in the Nose and Throat.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.
TUESDAY, March 13th.—5 P.M., Dr. Wilfrid Fox: Nævi.
THURSDAY.—5 P.M., Pathology Demonstration.

ST. PAUL'S HOSPITAL, Endell-street, W.C.
THURSDAY, March 14th.—4.30 P.M., Mr. W. K. Irwin: Pain in Genito-urinary Affections.

ROYAL INSTITUTE OF PUBLIC HEALTH, 37, Russell-square, W.C.
WEDNESDAY, March 14th.—4.30 P.M., Dr. R. Donaldson: Bacteriology in its Connexion with Forensic Medicine.

PEOPLE'S LEAGUE OF HEALTH.
WEDNESDAY, March 8th.—6 P.M. (at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, W.), Dr. A. F. Tredgold: Mental Deficiency.
FRIDAY.—6 P.M., Prof. V. H. Mottram: Common Errors in Diet.

ANCOATS HOSPITAL POST-GRADUATE LECTURES, Mill-street, Manchester.
THURSDAY, March 15th.—4.15 P.M., Dr. Langley: Exophthalmic Goitre.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.
TUESDAY, March 13th.—4.15 P.M., Dr. F. E. Tylecote: Calcium Therapy.
FRIDAY.—4.15 P.M., Mr. J. Morley: Demonstration of Surgical Cases.

UNIVERSITY OF SHEFFIELD POST-GRADUATE CLINIC
FRIDAY, March 16th.—3.30 P.M., Mr. Brockman: Thyroid Cases.

Appointments.

BARRON, H. THOMPSON, M.D. Lond., M.R.C.P. Lond., has been appointed Assistant Physician to the Skin Department, Westminster Hospital.
GROVES, E. W. HEY, M.D., M.S. Lond., to be one of the Medical Referees under the Workmen's Compensation Act for the districts of the Bristol, Wells, Weston-super-Mare, and Yatton County Courts.
NICOL, W. W., M.B., Ch.B. Aberd., Certifying Surgeon under the Factory and Workshop Acts for the Inverurie District of the County of Aberdeen.
RUDDOCK-WEST, T., M.D., Durh., D.P.H., Medical Officer of Health for the County of Norfolk.

Vacancies.

For further information refer to the advertisement columns.
Albert Dock Hospital, Connaught-road, E.—Res. M.O. At rate of £110.
Ayr County Hospital.—Sen. and Jun. H.S.'s. At rate of £100 and £80 respectively.
Belfast, City and County Borough of.—Med. Supt. Officer of Health and Port Medical Officer. £2000.

Birmingham and Midland Ear and Throat Hospital.—Second H.S. At rate of £150.
Birmingham and Midland Homœopathic Hospital and Dispensary. Hon. Anæsthetist and Hon. Consulting Ophth. S.
Brighton Borough Infectious Disease Hospital and Sanatorium.—Res. M.O. £350.
Cambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
Charing Cross Hospital.—Surg. Reg. £150. Also Asst. Surg.
Connaught Hospital for Walthamstow, Wanstead, and Leyton, Walthamstow, E.—Hon. Radiologist. Also Sen. and Jun. Res. H.S.'s. At rate of £150 and £100 respectively.
Croydon General Hospital.—Cas. H.S. £125.
Dreadnought Hospital, Greenwich.—H.P. At rate of £110.
East London Hospital for Children and Dispensary for Women, Shadwell, E.—Asst. S.
Hereford County and City Mental Hospital.—Second Asst. M.O. £350.
Hospital for Tropical Diseases, Endsleigh-gardens, W.C.—H.P. At rate of £135.
Hospital for Women, Soho-square, W.—Res. M.O. At rate of £100.
King's College Hospital, Denmark-hill, S.E.—Two Jun. Surgeons. Also Jun. P. for Dis. of Children.
Liverpool Open-Air Hospital for Children, Leasowe.—Jun. M.O. £200.
London Homœopathic Hospital, Great Ormond-street, W.C.—Fourth Anæsthetist. £50.
Manchester, Ancoats Hospital.—Clin. Asst to Ear, Nose, and Throat Dept. 10s. 6d. per clinic.
Manchester, St. Mary's Hospitals, Whitworth-street.—Four H.S.'s. Each at rate of £50.
Montana, Switzerland, Palace Sanatorium.—Asst. Phys. £400.
Newcastle-upon-Tyne, Hospital for Sick Children.—Jun. H.S. At rate of £100. Also Res. H.P. and Res. Sen. H.S. Each at rate of £95.
Nigeria, Medical Research Institute.—Biochemist and Protozoologist. £800.
Rochdale Infirmary and Dispensary.—Jun. H.S. £200.
Royal Dental Hospital of London, 32, Leicester-square, W.C.—House Anæsthetist. £200.
Royal Northern Hospital, Holloway, N.—H.P. and Obstet. H.S. Each at rate of £70.
St. Mary's Hospital, Institute of Pathology and Research.—Research Studentship. £200.
Salford Royal Hospital.—Two H.S.'s. Each at rate of £125.
Shanghai Municipal Council.—Second Asst. Commissioner of Public Health. Taels 600 per mensem.
Sheffield Royal Infirmary.—Ophth H.S. At rate of £80.
West London Hospital, Hammersmith, W.—H.P. and two H.S.'s. Each at rate of £100. Hon. Med. Reg. £100. Also Hon. Anæsthetist.
Westminster Hospital, Broad Sanctuary, S.W.—Asst. Surg. Reg. At rate of £50.
Weston-super-Mare Hospital.—Res. M.O. £130.
Willesden General Hospital, Harlesden-road, N.W.—Res. H.S. At rate of £100.
Windsor, King Edward VII. Hospital.—Hon. Ophth. S.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Haltwhistle (Northumberland), Erith (Kent), Exeter (Devon), and at Bervie (Kincardineshire).

Births, Marriages, and Deaths.

BIRTHS.

DAY.—On Feb. 26th, to Marjorie Semple, M.B., wife of William Day, Jun., College-road, Maidstone—a son.
FISHER.—On Feb. 27th, 1928, at a nursing home, to Grace, wife of Alfred George Timbrell Fisher, *M.C.*, F.R.C.S. Eng., of 59, Montagu-square, W.1—a daughter.
GABRIEL.—On Wednesday, Feb. 29th, at Colville, Gerard-road, Barnes, the wife of W. B. Gabriel, F.R.C.S., of a son.
VINER.—On Feb. 25th, at Chorley Wood, Herts, to Mona (née de la Mare), wife of Geoffrey Viner, F.R.C.S., of 27, Queen Anne-street, W.1—a son.

MARRIAGES.

AMIES—SPEIRS.—On Feb. 27th, at St. George's Church, Croydon, Cleeve Russell Amies, M.B., B.S., M.R.C.S., L.R.C.P., D.T.M., D.T.H., Malayan Medical Service, to Muriel, daughter of Mr. and Mrs. John Speirs, of Ashburton-road, Croydon.
LEE—COSTELLO.—On Feb. 28th, at St. Thomas's Church, Stockton Heath, Warrington, Major Robert Lee, I.M.S., to Frances Maureen, daughter of the late Mr. and Mrs. John Costello, of Tipperary, Ireland.

DEATHS.

FLETCHER.—On March 3rd, at Sudbury Farm House, near Harrow, Cavendish Fletcher, M.B., B.S. Lond., M.R.C.S., L.R.C.P.
JERMAN.—On Feb. 25th, Arthur Edward Jerman, M.B., D.P.H., T.D., late Lieut.-Col., R.A.M.C., T.F., for 24 years M.O.H. of Erith and district, aged 55.
PORTER.—On Feb. 27th, at The Avenue, Beckenham, Kent, Major-General Sir Robert Porter, K.C.B., C.M.G. (late R.A.M.C.), aged 70.
RIGDEN.—On Feb. 28th, at Alumhurst-road, Bournemouth, Walter Rigden, M.D.
SICHEL.—On Wednesday, Feb. 29th, at Vine House, Sevenoaks, Gerald Theodore Silvester Sichel, F.R.C.S., late Surgeon, R.N.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

THE CONTRIBUTION OF CHRISTIAN THOUGHT TO THE SCIENCE AND PRACTICE OF MEDICINE.

An Address delivered at the Dedication of the Pillar of Healing in St. Anne's Cathedral, Belfast,*

BY HAROLD BALME, F.R.C.S. ENG., D.P.H.,
FORMERLY PROFESSOR OF SURGERY IN, AND PRESIDENT OF, THE SHANTUNG CHRISTIAN UNIVERSITY, CHINA.

The Problem of Pain.

FROM the earliest days of human life on earth, the problem of pain and sickness has challenged the thought and faith of humanity. The mysteriousness of its origin; the uncertainty of its outcome; the crippling results of its ravages—these are some of the factors which constitute the essence of the problem, and which, in all ages, and amongst all people, have led to the same unanswered questionings as to the ways of God. There has always been something so inexplicable, so baffling, so portentous, about the onset of disease, and it is little wonder that it has readily given birth to nervous dread and apprehension, and has led to every kind of superstitious practice. Totem worship and secret cult, hidden charm and magic potion, votive offering and weary pilgrimage—all bear witness to the same pathetic efforts to appease an angry spirit, to ward off some noxious influence, or to counteract some unknown and impalpable evil, thus restoring health and vigour to a loved one. It has needed the vision of an Elizabeth Browning to see that—

> "Knowledge by suffering entereth,
> And life is perfected by death." [1]

or the inspiration of John Keats—once apprenticed to a surgeon—to appreciate the necessity of a world of pains and trouble, in order, as he put it, "to school the intelligence and make it a soul." [2] It has needed the genius of a Mrs. Hamilton King to ennoble suffering as an act of worship, of fellowship, and of needed discipline, so that men could say—

> "How poor were earth if all its martyrdoms,
> If all its struggling sighs of sacrifice
> Were swept away, and all were satiate-smooth:
> If this were such a heaven of soul and sense
> As some have dreamed of—and we human still.
> Nay, we were fashioned not for perfect peace
> In this world, howsoever in the next:
> And what we win and hold is through some strife." [3]

But not many have risen to such heights. To the vast majority sickness and pain have been twin spectres of dread omen, understood by few and feared by all.

The Contribution of Greek Thought.

It is part of the glory of the golden age of Greece that the leaders of that period—those "fearless mariners on the uncharted sea of thought," as Prof. Angus calls them [4]—dared to probe into the mysteries of disease, and succeeded in lifting the science and practice of medicine on to an entirely new plane of human endeavour. Two streams of thought converged upon the problem, the one religious, the other intellectual and scientific, but each flowing in complete harmony with the other. The religious stream had its fount of origin in the ceremonies associated with the worship of the God-physician Æsculapius—reputed son of the divine Apollo and the human maiden Coronis—and found its inspiration, for the most part, in the teachings of the old mystery religions, with their emphasis upon a benevolent, though remote, Deity, their yearning for redemption, and their idealisation of a beautiful body enshrining and harmonising with a beautiful mind.

The intellectual stream was the natural product of an age which bore such acute and accurate minds as those of Herodotus and Sophocles, Thucydides and Aristophanes, Socrates and Plato—all of them, be it remembered, contemporaries of him whom we have come to speak of as the Father of Medicine, Hippocrates of Cos. Looking back, as we do to-day, after the lapse of nearly 2400 years, it is easy to fall into the mistake of regarding Hippocrates as though he were some amazing human comet, born out of due time, and flashing upon his generation a brilliance of thought and intuition of incomparable splendour. But such was not entirely the case. Great pioneer as he undoubtedly was, Hippocrates was also, on the one hand, an inheritor

* The address will be issued as a booklet by the Student Christian Movement, 32, Russell-square, London, W.C. 1. Price 6*d.* through any bookseller.

of the trained observations of physicians like Democedes, or the generation of men who gave to Homer his accurate knowledge of anatomical detail, whilst on the other hand, he was a sharer in the intellectual stimulus of the great thinkers of his day.[5] The genius of Hippocrates lay in his power to build upon this foundation, to project into the physical sphere the same independent and fearless thinking as characterised the philosophers of his age, and thus to erect an edifice of scientific thought based upon close observation of natural processes and meticulous attention to clinical symptoms, and inspired with high idealism and lofty ethical code. In this way Hippocrates, and the school which succeeded him, made an invaluable contribution to medical progress. They delivered the investigation and treatment of disease from blind empiricism and superstitious priest-craft, they proclaimed to the world that all physical disorders were subject to natural laws, and they inspired the profession with a noble quest for ultimate truth and a lofty conception of ethical conduct.

And yet, as Sir William Osler used to remind us, although "the tap-root of modern science sinks deep into Greek soil," Hippocrates, with all his genius, did not go beyond highly trained observation and a conception of disease as a process of Nature,[6] whilst the religious thinking of the Greeks was largely pessimistic in outlook, knew nothing of conscience, nothing of a conception of the Kingdom of God, and possessed but little interest in the fate of mankind.[7]

The Coming of Jesus Christ.

It was thus to a world of mysterious suffering for which Grecian culture and piety could find no adequate solution, and to which the best religious thought of Judea had no higher interpretation to offer than that of "the fathers eating sour grapes and the children's teeth being set on edge,"[8] that the Son of Man came; and with His coming our whole conception of sickness and disease has been utterly transformed, and an entirely new motive in life provided. Christianity "lives by the glowing hope of a better world," to quote Albert Schweitzer's splendid phrase, and while Græco-Oriental mystery religions could only bid men "free themselves from the world," Jesus was telling them to get free in order to work in the world, in the spirit and in the love of God.[9]

Of the profound mystery of the Incarnation we shall never, perhaps, discover the full meaning, but one aspect of that mystery is patent to all eyes, for it lies illumined on every page of the gospel record. The Incarnation meant identification with common humanity, in all its frailty, its suffering, and its physical limitations. We see this sublime wonder in every detail of Our Lord's life among men—in the infinite tenderness with which He "bare our infirmities" and entered into the sorrows of the afflicted, as in the exquisite sympathy which compelled Him to stretch out His pure hands to touch the loathsome leper, and which made it impossible for Him to deafen His ears to the appeal of a Syrophœnician mother, or to pass, unheeded, the cry of a blind Bartimæus.

We see it anew in His solicitous care for the "little maid" whom He bade to arise from her deathbed, in His chivalrous concern for the sisters of Lazarus, in the "virtue" which goes out of Him as He heals the woman who touched the hem of His garment. But most of all we see it in His own experience of physical pain, in the bloody sweat which dropped from His brow in the night-vigil of the Garden, in the agony of martyrdom which drew from His lips those impassioned cries on the Cross of Calvary. "He shared pain," as T. R. Glover says in his "Jesus of History," "He sympathised with suffering; and His understanding of pain, and, above all, His choice of pain, taught men to reconsider it and to understand it, and altered the attitude of the world toward it."[10]

But it was not alone by His sharing of human suffering that Jesus has changed our conception of disease and pain. He did far more than this, for He brought to the world an entirely new revelation of God and of Man. Instead of a remote Deity, infinitely just and righteous, but far removed from the sorrows of humanity, Jesus Christ came to reveal a God Who was clothed with personality, a Father Whose whole being was Love, and One in Whose sight the most insignificant of His creatures possessed infinite worth. The God of Jesus was a God Who cared intensely for the welfare and happiness of His children, One Who planned for them a complete redemption of body, mind and spirit, and Who called them into the fellowship of the divinest of all services—the creation of a brotherhood of which Christ Himself should be the firstborn.[11] This was the evangel which Jesus Christ brought to the world, and it is in the inspiration of that message that numberless men and women have gone forth to lives of heroic endeavour and splendid sacrifice.

Let us now attempt to discover how far these new conceptions have affected the course of medical progress and have influenced the science and practice of medicine. We shall find traces of that influence in at least four different directions.

A New Valuation on Human Life.

In the first place, the Christian view of a God-controlle world has placed a new valuation on human life and pe sonality, such as is found in no other religion, and it is ou of this new sense of values that our hospital system, an all that is associated with the care of the sick and helples have sprung. "The chief glory of mediæval medicine, writes Dr. F. H. Garrison in his History, "was undoubtedl in the organisation of hospitals and sick nursing, which ha its origin in the teachings of Christ. For while the germ the hospital idea may have existed in the ancient Babyloni custom of bringing the sick into the market-place, f consultation as it were, and while the Iatreia and Asclepe of the Greeks and Romans may have served this purpo to some extent, the spirit of antiquity towards sickness ar misfortune was not one of compassion, and the credit ministering to human suffering on an extended scale belon to Christianity."[12]

It was during the reign of Constantine that the Asclepe were closed, along with other temples, and it was short after this time that the movement to found and bui hospitals sprang up—a movement in which Helena, t mother of Constantine, is said to have taken a promine part. In the year 369 one of the first of these institutio was established at Cæsarea by St. Basil, with hospital f the sick and houses for physicians and nurses. Six yea later a large hospital of 300 beds was opened at Edessa f plague-stricken patients, whilst a variety of philanthro institutions were founded, each with its separate title, f different classes of needy and destitute sufferers. Western Europe the first "nosokomeion"—as the ordina hospital came to be called—was established about A.D. 4 by Fabiola, a Christian lady of Rome, its purpose being, St. Jerome informs us, "to gather in the sick from the stre and to nurse the wretched sufferers, wasted with pover and disease." It was the religious orders and fraterniti which were growing up in the Christian Church at this tin which founded and maintained these institutions, whe as Mrs. Hamilton King beautifully describes it:—

> "A small part only of the house served
> The brethren's needs; but all the larger rooms,
> Lofty and bare, they made their hospital,
> In which by night and day they ministered
> Unto their sick: and these were always full.
> And all of them had diligently learned
> The art of healing, and among them were
> Some surgeons and physicians much expert."[13]

From the thirteenth century onward this practice mercy has overflowed the borders of the Christian Chur and has gradually permeated the whole of our national l so that we no longer think of hospital practice as a du confined to religious bodies. But let us never forget th the instinct which impels men and women to-day to to the help of the sick and wounded, the instant respo to a call of need which drove aviators and sleigh-driv hundreds of miles last year, in the teeth of a sixty-mile-p hour blizzard, to take antitoxin to the diphtheria patients far Alaska, the compelling force which leads a sea capt to change his course in order to carry medical aid to so sick man on the ocean—these instincts all find their ori in the new valuation of human life and sacrifice which Red Cross flag for ever symbolises.

Nor is this new valuation of human life confined to physical nature of man, for the very heart of Christ's mess was His insistence on the essential unity of all parts of ma being, physical, moral, and spiritual, and on the need of e for that complete redemption which He had come to bri By its insistence on this unity, and on the influence wh body, mind, and soul exerts the one upon the other, Christ thought has concentrated attention on a vital fact, importance of which is being recognised more and m to-day by every guild of health and by every student medico-psychology.

A New Motivation for Medical Research.

In the second place, it may fairly be claimed that quest for truth, which, as we have seen, has come down to as a magnificent legacy from the Grecian school of thoug has received a new connotation as a result of the life teachings of Jesus Christ. To the man who has caugh vision of the full significance of life as Jesus saw it, or w all unconsciously perhaps, has come under the pervad influence of His teaching, this quest becomes a verita crusade, the end of which is not a mere discovery of hith unknown facts, but the forging of a new weapon with wh to alleviate the sufferings of a stricken humanity. "I co shout for joy," writes Walter Reed to his wife, as he succ fully concluded his important investigation of yellow fe at Panama. "The prayer that has been mine for 20 ye that I might be permitted in some way, or in some time alleviate human suffering, has been granted."[14]

It is a thrilling story, this patient search for the causa and cure of disease. "To wrest from nature the sec

which have perplexed philosophers in all ages, to track to heir sources the causes of disease, to correlate the vast stores f knowledge that they may be quickly available for the revention and cure of disease—these are our ambitions," eclares Osler in one of his noblest addresses,[15] and in these pt words he gives us the life-history of that splendid corps f scientific investigators to whom the whole world stands ebtor to-day. William Harvey, the man who avowed imself "the partisan of truth alone," diligently tracing ut the circulation of the blood; old Antony Leeuwenhoek, he Dutch draper, grinding the first lenses which revealed he existence of micro-organisms, and paving the way for he brilliant achievements of a Louis Pasteur in France, Joseph Lister in Britain, a Robert Koch in Germany; lumphry Davy and Horace Wells, Morton, Jackson, and ur own great-hearted James Simpson, all sharing in the iscovery of anæsthetics, those God-given drugs which nable the surgeon of to-day, in Weir Mitchell's immortal hrase, "with God-like will to decree the death of pain"[16]; averan, finding the malaria parasite, and Manson and Ross nd Grassi, after infinite labour, completing the whole story malarial infection and its cure; Castellani and Sambon erforming the same service in the case of sleeping sickness; arroll and Lazear, Reed and Gorgas, ridding the world of s fear of yellow fever, as Jenner had rid it of the peril of nall-pox; James Mackenzie, working in humble obscurity r 20 long years at those laborious researches which have volutionised our knowledge of cardiac disease; Ehrlich, at great plodding genius, adding experiment to experiment til he presents humanity with a means for destroying thogenic spirochætes.

So might we continue, for the tale is not half told of the en and women whom the profession loves to honour, to y nothing of that still larger army of "silent workers who, ten unknown and neglected by their generation, kept ve the fires on the altars of science, and have so opened e doors of knowledge that we now know the laws of alth and disease."[17]

An Inspiration to Heroic Service.

In the third place, may we not say that the tradition nich has come down to us from the sacrificial life of Jesus rist has been one of the most potent factors in inspiring n and women to undertake hazardous and devoted acts service for their fellows, with utter disregard of personal nger? The roll of honour of the medical profession, and its sister-profession of nursing, is a record of which we may ll feel proud, including, as it does, not only the names of se who have actually given up their lives in the pursuit science and the service of humanity, but also of hundreds re who "jeoparded their lives unto the death in the h places of the field."[18]

Emblazoned on that roll are the names of scores of entists who gladly risked life and health and reputation the course of their research—Haffkine, inoculating iself with his own plague and cholera vaccines before he uld risk the lives of others; Carroll and Lazear, subtting to the bites of the venomous yellow fever-bearing squitoes (an act which cost Lazear his life); Prowazek, Russian investigator, perishing of typhus fever from the e of an affected louse; Thuillier, of the French Comision, carried off by cholera in the midst of his investigation the terrible epidemic of 1883; Joseph Dutton, dying the Congo whilst tracking the causation of sleeping kness. We think also of the sublime moral courage of steur, as he staked his great scientific reputation on the cess of those experiments which were to mean so much a suffering world; of Lister, with "faultless patience unyielding will"[19] calmly facing ostracism and ridicule his fight for the mastery of sepsis; of Hall Edwards and cker, of Bergonié and the scores of other physicians and ntists who have suffered the loss of limbs or of life itself ilst experimenting with the all-powerful Rontgen rays.

nd what shall we say of the men and women who have ed their all in the common service of suffering humanity—David Livingstone, shaking with fever as he tramped ough the African jungle; of Pennell, dying with septicia in the attempt to save the life of a beggar on the han frontier; of Wilfrid Grenfell, battling with Arctic rms on the Labrador coast; of Elsie Inglis, dying of r exhaustion after her magnificent service to the stricken bians; of Edward Wilson, Scott's "best of comrades and nchest of friends" on the immortal South Pole Expediti; of Albert Schweitzer, gladly surrendering a world-e reputation as theologian and musician in order to our the dwellers in the primeval forest; of Father nien and Arthur Jackson; of Florence Nightingale and th Cavell? And what of that gallant company of surgeons nurses of all nationalities who performed incredible s of valour and of endurance as they tended the wounded ng the Great War? The line of medical and scientific es in the cause of humanity has never been broken, as we bow our heads in reverent memory of those who willingly gave up their lives in this royal service, we can use no more fitting words than those of the great epic of the eleventh of Hebrews: "These all died in faith, not having received the promises, but having seen them afar off. . . . Of whom the world was not worthy"

A Compelling Sense of Trusteeship.

But there is a fourth contribution which Christian thought has made to the science and practice of medicine, and one which is perhaps the greatest of all. It is the conviction of trusteeship which characterises every true scientist and physician and nurse, both with regard to the knowledge which they have acquired by individual effort, and also the ability to alleviate suffering and cure disease which training and experience have placed in their hands.

We have only to look round the world to-day, and especially those portions of it which have not yet come under the dominance of Christian teaching, to realise how much we owe, in our public life and in our social relationships, to this essentially Christian conception. In every act of Our Lord's crowded days, as well as in the profound lessons which He gave to His followers, we find repeated emphasis on this divine view of life. It forms the central theme of the symphonic music of Christ's last recorded parables—those striking word-pictures of the Ten Virgins, the Talents, and the Sheep and Goats. The failure of the maidens who had no oil in their vessels, of the steward who so carefully wrapped up his master's talent in a secure place of concealment, of the respectable company who were not interested in philanthropic efforts—what was it but an essential failure in trusteeship; for the lamps were entrusted to them for the purpose of shedding light in the dark watches of the night, the talent was intended for investment and profit, whilst the hungry and naked, the sick and imprisoned, whom the busy passed so heedlessly by, were no other than the little brothers of Our Lord.

To the medical and nursing professions there has been given, in no ordinary measure, this conviction of trusteeship, largely as a result of the influence of Christian thought, and never perhaps has this been acknowledged in more beautiful or adequate language than that employed by him whom we love to call the Father of British Clinical Medicine, the great Puritan doctor, Thomas Sydenham. Writing in 1666—the year preceding the publication of Milton's "Paradise Lost"—Sydenham prefaces the first edition of his monumental work on "The Cure of Fevers" with these noble words—his "*religio medici*," as Sir George Newman calls it:—

> "Whoever applies himself to medicine should seriously weigh the following considerations: first, that he will one day have to render an account to the Supreme Judge of the lives of sick persons committed to his care. Next, whatever skill or knowledge he may, by the divine favour, become possessed of, should be devoted above all things to the glory of God, and the welfare of the human race. Moreover, let him remember that it is not any base or despicable creature of which he has undertaken the care. For the only-begotten Son of God, by becoming man, recognised the value of the human race, and ennobled by His own dignity the nature He assumed."[20]

Thus, throughout the ages, as we trace the whole wonderful story of medical progress, we see, in countless ways, the pervading influence of the Divine Son of Man; and though we readily acknowledge that many of those to whom we owe unbounded gratitude for their magnificent contributions to the march of science would hesitate to claim for themselves the title of Christian, we cannot fail to see, in their lives and in their character, the reflection of Him Who came not to be ministered unto but to minister, and to give His life a ransom for many.

MATERNAL MORTALITY.

AT a conference held at the Central Hall, Westminster, on Feb. 28th, under the presidency of Dame Edith Lyttleton, a message was read from the Queen, expressing her concern at the continued high maternal mortality-rate and her conviction that concerted action should be taken. The following resolution was afterwards proposed from the chair and carried unanimously:—

This meeting recommends: That steps should be taken to obtain a medical inquiry into every maternal death due to childbirth; that the attention of the authorities responsible for the education of medical students should be drawn to the need for further training and experience in midwifery as a preliminary to general practice in medicine; that an official committee should be set up to advise upon the whole question of the training and employment of midwives; that action should be taken in every area to induce all local authorities to make their maternity services adequate; and that the provisions of the National Health Insurance Acts should be readjusted and extended so that medical and midwifery services should be available for mothers both for antenatal care and during and after confinement.

Dr. J. S. Fairbairn, during the discussion, said he would have preferred a greater degree of emphasis on the need for research which he regarded as the crux of the whole matter. Puerperal fever was the cause of at least one-third of all deaths connected with childbirth, and there were many points about it which were still obscure—how far it was due to infection already in the woman herself, in how many cases it was carried to her by the attendant, how resistance varied in different patients and in the same patient at different times, and so on. He set great value on midwifery as the foundation of a good maternity service. In all branches of medicine the first object was to secure natural function, and the midwife has an important share in promoting natural childbirth. The women themselves should be made to realise that there was a price to be paid for shortening their time of trial. Morbidity increased where interference with the course of Nature was practised. Great advances had been made in the training of midwives, and Dr. Fairbairn specially commended those cities, such as Newcastle, Birmingham, and Leeds, in which the Universities had taken it up. This gave the students the great advantage of having specialist lecturers and demonstrators instead of being dependent on one or two teachers for their whole course.

The importance of research was again dwelt upon by Dr. Ethel Bentham, but she urged that research should cover not only the circumstances of confinement, but the whole surroundings of the woman. There were two unfortunate gaps in the health service, one between the ages of 14 and 16, and the other at the early part of married life. During a period of 12 years' work at antenatal clinics Dr. Bentham had seldom seen a perfectly healthy young woman among those who came for examination.

Several speakers pleaded for better training of medical students. One or two who had had experience of country districts pointed out that it was no good telling the women they ought to have antenatal care if the local practitioners were either incompetent or unwilling to give it, and that antenatal clinics, specialist care, and hospital accommodation were alike worthless unless the local doctors were ready to avail themselves of the facilities offered.

MAJORCA AS A HEALTH RESORT.

To the Editor of THE LANCET.

SIR,—For some years past the number of foreigners coming to Majorca has been increasing. While many of these are tourists of the variety who wish to "do" the island in so short a time, and with so little fatigue to body and brain as possible, many stay for the winter months and a good number are invalids, sent out by doctors from more inclement regions to enjoy our equable climate, where during the winter the temperature is very rarely below the freezing-point, it never snows, and there are few rainy days. I wish to draw attention to a few of the conditions for which this island is suitable and to a few for which it is not as a rule desirable.

It has already been pointed out by medical writers that Majorca is peculiarly good for cases of arthritis, sciatica, gout, and the various ailments vaguely termed rheumatism. For all such ailments a dry sunny climate, such as we enjoy here, is almost invariably very beneficial. Sea-bathing can be indulged in, even by invalids, from April onwards, and is often extremely useful as an adjunct to open air and sun treatment. The island has a reputation, many centuries old, for being a good place for asthma, and, though not always suited to all cases, many of these patients do well, and bronchitics nearly always improve. On the other hand, the climate frequently does not suit cases of pulmonary tuberculosis, quite apart from the fatigue of the long journey and the inadvisability of sending such patients a long way from home. Patients who suffer from dyspepsia, gastritis, or other digestive troubles, if they intend to make a long stay, should take a house or flat, as Spanish food is apt to disagree with English people. Mallorquin cooks soon pick up English methods of cooking, and as a rule they cook well. For sufferers from habitual constipation this island is excellent; we have abundant supplies of good fruit and vegetables all the year round, much of the cooking is done in oil (our olives are famous), and in addition to these aids to evacuation there is hardly a day when it is not possible to take exercise, not only in the open air but in sunshine.

Palma itself is not a good place for organic heart affections; there are not many flat walks: there are no gardens or public parks to walk or sit in, and the patient who is unequal to walking up hill does not get much exercise. The bays of Pollensa and Alcudia give plenty of scope for walking on the flat, as well as for boating and sea-fishing, and there are hotels at both these places.

The climate of Majorca, the clearness of the air, the wonderful beauty of much of the sea coast, all make it an exceptionally good seaside place for a winter rest-cure for those to whom a winter in England means a period of staying indoors, if not actually ill, at least unable to brave the rigours of fog, snow, and east winds.

I am, Sir, yours faithfully,

P. GIMÉNEZ OLIVEROS.

Palma, Majorca, Feb. 19th, 1928.

NEW PREPARATIONS.

Magnolax Brand (Wampole) is an emulsion of the liquid paraffin of the British Pharmacopœia and of hydrate of magnesia; it contains no addition of laxative drug, sugar, or alcohol, and its action is to maintain easy and thorough evacuations. The preparation is made in Canada by Messrs. H. K. Wampole Company, of Perth, Ontario, and is distributed through Newbery's Agency, 31-33, Banner-street, London, E.C. Not being absorbed at all, it is regarded as safe in all circumstances, an interesting claim being supported for its value as a laxative in pregnancy, where the doses must be regulated by the physician in charge.

Felsol is a colourless crystalline powder, acid in reaction and easily dissolved in warm water. It is put on the market by the British Felsol Co., Ltd., 29, Red Lion-square, London, W.C., who have obtained considerable direct evidence from British practitioners of its value in the treatment of bronchial asthma and chronic bronchitis. It contains iodopyrin, antipyrin, and caffeine, and is supplied in powders whose contents are regulated so that one, or perhaps two, powders are generally required to check the asthmatic attack, it being suggested that the second powder should not be given till after an interval of two or three hours. The remedy can be taken in gradually decreasing doses as the patient recovers, and the doses can be increased where the condition is severe or obstinate; but instructions accompanying the powders give the wise warning that all such general directions are subject to special prescription by the doctor in attendance. We learn that nine special and general hospitals, two of them being well known and large London institutions, have made successful trial of the preparation.

CARE OF DUBLIN SCHOOL-CHILDREN.

Dr. Mary O'Leary, one of the recently appointed medical inspectors of school-children for the city of Dublin, has been giving to a newspaper representative a description of her work and some of her first impressions. She said that there was a three-fold object in the work: (1) to discover diseases and defects in school-children, (2) to arrange for the cure or correction of these, and (3) to prevent disease. The last was the most important of the three. In the two months during which the two inspectors had been at work 3000 children had been examined. Of these 80 per cent. had some defect, most of which could have been prevented. Ten per cent. had eye trouble and 60 per cent. decayed teeth. Children with minor deformities, such as rounded shoulders, curvatures due to faulty position, and mouth breathers and stammerers were taught simple exercises for the correction of these defects. During each child's examination a simple health talk, suitable to the child, was given. A list of "backward" children was being made, and it was hoped that in time special classes could be formed for them in which manual instruction could be given, and the children, even if remaining almost illiterate, might be made self-supporting. The children were examined in three groups: (1) entrants, 5 to 6 years; (2) intermediate, 8–9; (3) leavers, over 12. In this way every child would be examined three times during his school life.

AN AID TO DEFÆCATION.

Dr. E. P. LEAVY (Innisfail, Queensland) writes: Of the many "urges" known to the constipated might I suggest a final psychic one after the failure of the various "Walcher positions"—viz., the crushing and rolling effect of paper preparatory to its use.

Goulstonian Lectures

ON

SOME PROBLEMS OF NEPHRITIS.

The First Goulstonian Lecture in 1928 delivered before the Royal College of Physicians of London on March 13th

BY T. IZOD BENNETT, M.D. LOND.,

FELLOW OF THE COLLEGE; PHYSICIAN TO OUT-PATIENTS, MIDDLESEX HOSPITAL, AND TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

LECTURE I.—THE PROBLEM OF URÆMIA.

THE more one studies nephritis, the more is one aware of the extreme complexity of the subject, and any attempt to review the problems of uræmia must be tentative, although I feel that recent work has thrown new light on the mechanism governing some of the phenomena which we group together under this heading. A great variety of symptoms is by different writers included under the heading of uræmia, and at the outset I feel we must make distinction between those which occur where both ureters became simultaneously blocked, or when a single functional kidney is accidentally removed, and the train of symptoms which characterises the termination of a case of nephritis. The former syndrome is usually marked merely by slowly deepening coma, whilst in the latter are seen, in classical form, not only the gastro-intestinal symptoms, but also the muscular twitchings, the convulsions, and often the hyperpnœa, which form for most of us the picture of true uræmia.

I propose to describe some typical biochemical observations from a case of this latter type, and after endeavouring to demonstrate those aspects which I feel to be of true importance in the production of the peculiar nervous phenomena of uræmia, I shall describe some recent experimental work which appears to be of importance in this connexion.

A CASE OF RENAL FAILURE.

The original custom for the Goulstonian lecturer to give a demonstration on some dead body, "to be then and there dissected for the disease treated in the lectures," has for many years fallen into disuse. But I may perhaps be permitted to begin my lecture by describing a case which illustrates in many details the problems before us.

The patient, a woman then aged 42, came under my care in 1923 complaining of abdominal discomfort associated with a tumour in the right side which was rapidly increasing in size. Albumin was present in small quantities in the urine, and the blood showed marked retention of nitrogen. It was decided after consultation that an exploratory operation should be performed. This was carried out by my colleague, Mr. John Murray, and revealed extensive cystic disease of both kidneys, although the left was so much less enlarged than the right that it had not been palpable before operation. The incision was closed and nothing further was done, recovery from the operation being quite straightforward.

Course of the Disease.

At her earnest request a clear explanation of the condition and its probable consequences was made to the patient, who was a person remarkable both for her intelligence and philosophy. For two years already she had complained of constant dryness of the mouth with a peculiar taste, as well as of some diminution in her bodily strength. She was advised to abstain as much as possible from foods containing a large proportion of protein, and returned to her home. Two years later she consulted me again and was placed on a diet containing a very high proportion of carbohydrates. At this time the right kidney had increased considerably in size and the left had become readily palpable. There was considerable loss of strength, so that she was obliged to lead the life of a semi-invalid, rising for not more than six hours daily and seldom walking as much as one mile on any day. She returned home, where she lived chiefly upon green vegetables, biscuits, and farinaceous food, and gradually declined in vigour until the middle of last summer, when she again came into hospital for closer observation. I feel it my duty to record the fact that this lady was so desirous to be in any way of service to others who might be ill, that for four years she placed herself at my disposal for any investigations which I might feel to be of possible utility.

At the time of her final admission to hospital in the summer of last year, her appearance was, on the whole, healthy, although there was a slight puffiness below the eyes, and the legs, although not pitting on pressure, had a somewhat swollen appearance. She was rather deeply freckled and pigmented, which made her aspect deceptively healthy, for she was so weak that it was impossible for her to walk more than 100 yards, and dyspepsia with occasional vomiting, together with attacks of breathlessness during the night, were making her life uncomfortable. Although she could give an astonishingly clear account of her symptoms, she stated that her brain felt as if it were in a fog, and that consecutive thinking was difficult for her. She gave a graphic account of the constantly bitter taste of her saliva, and complained of a frequent sinking feeling and faintness between meals. On examination there was no obvious hypertrophy of the heart, though the blood pressure was 100 diastolic and 180 systolic. The renal tumours were very large, distending both flanks; the right remained larger than the left. Polyuria was present, but disturbed her very little, and her sight was entirely unimpaired, there being no changes whatever in the fundus oculi.

Treatment and its Effects.

My first endeavour was to alleviate her nausea and tendency to vomit, and this was accomplished by still further curtailing her diet, so that she lived for several weeks on nothing but tea without milk, orange juice, and dry biscuits, the total value of the diet being something less than 600 calories a day. On this her gastro-intestinal symptoms were indubitably less acute, but she was hungry and felt her weakness to be increased, and I was accordingly obliged to revert to the somewhat more generous diet she had previously taken. Her condition as regards nitrogenous bodies in the blood up to this time is shown in Table I.

TABLE I.

—	Dec., 1923.	March, 1925.	Oct., 1926.	June, 1927.	Sept., 1927.	Oct., 1927.
Blood-urea ..	50·6	64	68	105	90	146
Non-protein N. ..	41·9	84	52	75	96	108
Creatinine ..	1·8	2·1	2·5	3·4	4·6	6·1
Uric acid.. ..	2·9	3·6	4·8	—	3·8	2·6

(In this and subsequent tables, unless otherwise mentioned, figures represent milligrammes per 100 c.cm.)

These figures also show the upward trend of the commoner nitrogenous bodies up to the time of her final admission. The last three columns suggest that the very restricted diet had exerted some influence in reducing the concentration in the blood, but this possible improvement was abruptly lost, as shown by the high figures in the last column, when the more generous diet was resumed. Until the end of October the clinical condition was unchanged and arrangements were then made for the patient to return to her home.

The Final Phase.

In a recent essay dealing with the phenomena of uræmia, Sir John Rose Bradford has described the abrupt and dramatic violence which sometimes characterises the onset of the final uræmic symptoms. Such was my experience in the present case, for in the early morning of Nov. 2nd, 1927, the patient was seized with violent convulsions followed by unconsciousness. Within an hour she had apparently recovered and, though a little frightened, gave a clear account of her symptoms and described how the twitching of her muscles, which was now very apparent, had first been observed on the previous day, when some stiffness of the limbs and occasional aching in the back had troubled her. The blood pressure remained in the region of 150 mm. systolic, and a full half litre of urine was passed. This condition, of clear consciousness with sharp twitchings of the muscles, remained unchanged for a further 24 hours, and it is worthy of mention that her mental state was one of entire comprehension of her situation; she talked cheerfully and with full intelligence, and was at pains to call the sister of the ward and to give instructions that both my friend, Prof. E. C. Dodds, and myself were to be allowed to take any specimens of blood or cerebro-spinal fluid we might desire at any time, and that we were to have full liberty to carry out complete post-mortem examination if she should not survive.

During that night several severe fits occurred, between which the patient was only semi-conscious, and the muscular twitchings were very noticeable. She complained of extreme pain in the back, apparently due to the convulsive contraction of the erector spinæ muscle. Calcium lactate in doses

of grs. 5 and sodium bicarbonate in doses of grs. 60 were given hourly during the following day, and more than one pint of urine was passed during the same period.

Apparently as the result of this treatment, consciousness was regained, and during the next 24 hours twitching was less marked; the patient could reply to all questions, although her mental state was very confused. She drank fluids freely, and passed fair amounts of urine, although incontinence was present. Drowsiness reappeared on the night of Nov. 5th, and convulsions became frequent, with almost complete unconsciousness between the attacks. It was felt that there was no justification in proceeding to intravenous medication and, therefore, no further alkali was given during the day of Nov. 6th, when the patient lay in coma. One convulsion occurred at 6 P.M., and death followed an hour later.

The following table shows the nitrogenous constituents of the blood during this last phase.

TABLE II.

COMMENTARY.

The case which I have related is one which has been selected purposely as illustrating several important points. In the first place, it seems to me of value in that it is an example of pure and progressive renal failure terminating in uræmia, without being a case of true nephritis. Short of deliberate experiment, it is difficult to imagine circumstances by which the effects of slow destruction of kidney substance could be produced as accurately as is done by this strange disease.

It is not my purpose to enter into discussion of the pathology of cystic disease, for it is impossible yet to formulate even a plausible theory to account for this affection, but rather I would ask you to consider with me in detail the main symptoms which affected this patient, with a view to deciding to what degree we can explain the mechanism by which they were produced.

Until the last four days of her life she was really seriously troubled by two sets of symptoms only: first, those of progressive weakness; and secondly, nausea, anorexia, and especially a foul and sour taste in the mouth. It is plausible to suggest that the weakness was largely the result of the low diet on which she was obliged to live, whilst the disorders of appetite and taste were almost certainly the result of the over-saturation of the blood with urea and kindred nitrogenous substances. The account of the taste, given by the patient, was a very exact description of that of urea, and the following analysis of her saliva, compared with that of normal persons, as reported by Dodds, supports this belief very strongly.

TABLE III.—*Analysis of Nitrogenous Constituents of Saliva.*

	Ammonia (as N).	Urea.
Normal average	6·3	9
Uræmic patient	75	41

It is perhaps of particular interest that neither œdema nor hypertension was present in more than slight degree, but to these facts I shall revert later.

Returning to the events of the last five days of her life, we are faced with the classical phenomena of acute uræmia, with its two customary and interwoven symptoms—convulsions and coma. These symptoms are clearly referable to the central nervous system, and with them we must discuss the muscular twitchings which were a prominent feature of the terminal period, even at times when the brain was clear. The progressive coma typical of calculous anuria and of complete excision of the kidneys has long been distinguished from the twitchings and fits of certain other cases. Possibly the present case should be regarded as exhibiting both these types intermingled. But it is essentially the muscular twitchings and convulsion which place the present case in the category of tru uræmia, and it is my desire to see to what extent thes symptoms can be explained by observations on th changes in the body fluids which occur in suc subjects.

NITROGEN RETENTION.

Perhaps the most popular explanation of uræmi is that it is the direct result of the accumulation urea and kindred substances in the blood. Brigh himself was to some extent the originator of th theory. In his Goulstonian lectures, delivered in 183 he said: "What seems in some way to account f the general derangement and suffering of the constitu tion is the fact that urea becomes demonstrable in th circulating mass, and the blood becomes impregnate with that substance."

In the 95 years which have followed, this conceptio of the significance of urea retention has been amplifie We have learnt that urea is but one of the nitrogenou bodies which accumulates in the blood in nephriti and we have learnt that a similar retention occu in the case of certain non-nitrogenous substance Towards the beginning of the present century th study of this aspect of nephritis was given a fres impetus by the work of Widal and Javal, who intr duced more accurate methods of blood analysis, an of Achard, whose recent summary of the subject a model of clear exposition. This work appears have focused the attention of many French observe to an extent that is perhaps excessive. For thoug we all realise to-day that the retention of nitrogenou substances in the blood is an invaluable help in th diagnosis of renal failure, and though we apprecia the fact that high nitrogen figures may become great prognostic importance, we also realise th nitrogen retention by itself offers no explanation the actual phenomena of uræmia. Without enterin into the bulky literature of this subject, I venture t summarise the chief reasons against nitrogen retentio being the cause of uræmia as follows.

1. The administration of urea and kindred substances animals does not produce uræmia.
2. Conditions such as cystic disease of the kidney prostatic obstruction often persist for years with mark nitrogen retention but no evidence of uræmia.
3. Cases of uræmia without nitrogen retention a occasionally observed.

RETENTION OF NON-NITROGENOUS SUBSTANCES.

The retention of nitrogenous substances in th blood is marked in renal failure largely becau they are quantitatively amongst the more importa substances which the kidney is normally called upo to excrete; but evidence accumulates to show th other chemical substances will show increased co centration in the blood, although to a lesser degre Thus de Wesselow has published interesting observ tions on the high concentration of phosphates se in uræmic patients, and in a more recent study he h confirmed and elaborated the work of other observe which demonstrates that even sodium chloride excreted with difficulty, and tends to show increasing concentration in the blood in these case The blood analyses in the case I have described to yo were in full agreement with these findings, the actu figures in the terminal phase being as follows:—

TABLE IV.

	Blood phosphorus (normal, 2–3).	Blood chlorides (normal, about 50
Nov. 2nd	6·3	503
„ 4th	6·2	561
„ 5th	8·3	568
„ 6th	8·5	553

Andrews has recently called attention to a curio diazo-reaction given by the blood and cerebro-spin fluid in cases of uræmia; this reaction was positi also in my case. It has been shown by Blotner a Fitz to appear rapidly in dogs after nephrectomy, a though its significance is still obscure, it seems ve

possible that this again is an example of the retention and concentration in the blood of some substance which the normal kidney would excrete. Whilst admiring the patience and ingenuity with which biochemists have inquired into these problems, we are bound, I think, to admit reluctantly that at present no direct relation has been shown to exist between the accumulation of any of the chemical bodies I have discussed and the nervous phenomena of uræmia.

Acidosis in Uræmia.

If now we turn our attention to other aspects of the blood chemistry in renal failure, we find that acidosis is almost invariably an accompaniment of this state. I use the word acidosis in accordance with the suggestion of the Medical Research Council to denote a lowering of the alkali reserve of the blood.

The work of Palmer and Henderson, of Weil and Guillannin, of Mogena and Orcoyen, may be quoted as typical observations amongst many which confirm the view that acidosis can be demonstrated in all cases of uræmia in which nitrogen retention is present and especially in those with marked nervous and respiratory symptoms. My patient with cystic disease of the kidneys was no exception to this rule, for the alkaline reserve estimated shortly after the onset of her terminal symptoms stood at the low figure of 12·6, and subsequent estimations are shown in the following table:—

Table V.—*Alkali Reserve in c.cm. of CO_2 per 100 c.cm. Plasma.*

Nov. 2nd	12·6	Nov. 5th, 10 A.M.	48·5
„ 3rd	13·7	„ 5 P.M.	55
Nov. 4th, 5 A.M.	20·9	Nov. 6th, noon	56
„ 10 A.M.	28·7	„ 7th (autopsy)	18·2
„ 9 P.M.	36·8		

The gradual increase in the alkali reserve which occurred in later days was the result of the administration of large doses of sodium bicarbonate which was instituted about 12 hours after the first convulsion. The effect on the patient's general condition was very marked at first, but passed off after the third day. Muscular twitchings never completely disappeared, although they became less noticeable, the general effect being a restoration to full consciousness. We must, however, observe that this amelioration was only temporary, that the muscular twitchings were never entirely suppressed, and that in spite of the improvement in the acidosis, coma and convulsions returned and became irremediable. The logical conclusion is that the condition of the blood alkali is not by itself a cause of the neuromuscular phenomena, and the absence of such symptoms in other conditions of acidosis makes it probable that here once more we have been following a false trail.

Possible Importance of Calcium.

If we resume our search for a chemical explanation of uræmia, having discarded those substances which are in excess in the blood and having put aside acidosis as an explanation, is there any other feature of the blood chemistry which may possibly throw light on the problem? Blood analysis is usually confined to a limited group of substances, but there is one amongst them which we have not yet examined, and which may have an important bearing on uræmia. I refer to calcium. We are here on very difficult ground, for though actual estimation of the calcium content of blood is not unduly difficult the problems surrounding the actual physical state of calcium in the blood, the relation, for example, between the ionised and total calcium, are extremely intricate, so that an interpretation of the figures is at present very nearly impossible. In the work of de Wesselow, which I have already quoted, attention was drawn to the diminution in the calcium content of the blood which accompanied the increase in the phosphates. Such a diminution was very marked in my case of cystic disease, the calcium of the blood, which is normally from 10–12 mg. per 100 c.cm., being reduced to 6 mg. or even less. This low figure was found to persist throughout the terminal phase of the patient's illness, and was not apparently influenced by the improvement in the acidosis which followed the administration of sodium bicarbonate. The actual calcium figures are shown in the following table:—

Table VI.—*Calcium Content of Blood.*

Normal average .. .. 10–12.

Uræmic patient	Nov. 2nd	6·6	Nov. 6th	5·9
	„ 4th	6·5	Post-mortem	8·9
	„ 5th	6·5		

I have already said that in the present stage of our knowledge it is impossible to draw any permanent conclusion as to the meaning of these low calcium figures in uræmia, but I think that reflection on the phenomena observed in certain other clinical states in which the calcium of the blood is reduced is somewhat suggestive.

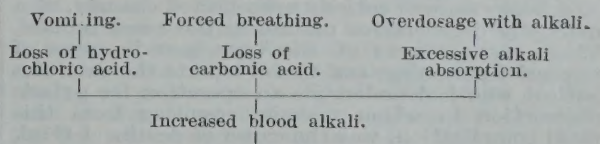
Tetany.

The group of cases in which a distinct reduction of the blood calcium is most marked is surely that in which are to be seen the symptoms described as tetany, and tetany is found to occur in a large number of apparently dissimilar diseases, the chief of which are: (*a*) non-malignant pyloric stenosis; (*b*) parathyroid deficiency; (*c*) chronic diarrhœal states; (*d*) rickets; (*e*) poisoning by overdosage with alkalis.

I recall, for example, an interesting patient with pronounced vomiting as the result of pyloric obstruction of obscure origin. She suffered from tabes, and was at first believed to have gastric crises; but fuller investigation showed that practically nothing could ever pass through the pylorus. The barium meal upset her greatly, and after several hours, during which she was in a semi-fainting condition, she exhibited muscular irritability, and I was called to her at a time when she lay in a condition of complete carpopedal spasm with the classical flexion and extension of joints characteristic of severe tetany. A subsequent operation revealed a curious thickening at the obstructed pylorus which was possibly of gummatous origin.

Amongst other causes of tetany we must note that it has been produced experimentally in man by forced breathing over long periods, and in certain cases where the therapeutic administration of alkalis has been pushed to an extreme point. In such examples it is easy to demonstrate certain chemical factors which are constantly present and which I have endeavoured to indicate in the accompanying table.

Table VII.



Calcium reduction and tetany.

It will be seen from examination of this table that all the cases in this group have three factors in common: first, alkalosis; secondly, tetany; and thirdly, a reduction in the calcium content of the blood.

Reverting to the conditions in which tetany is commonly encountered it is, of course, established that some connexion often exists between this condition and a deficiency of the parathyroid glands; its occurrence in certain diseases of children, such as rickets and cœliac disease, is also well known; whilst even in adults it is an occasional finding in conditions of chronic diarrhœa. Dr. Jean-Charles Roux recently showed me a very interesting case at the Hôpital Vaugirard in Paris. The patient was a woman who for many years had had constant diarrhœa, with loose stools containing a large proportion of all the ingested fat. The pathology of the case was obscure. For many months she had suffered from tetany, often latent, but sometimes showing itself acutely; its

main manifestations were always rapidly relieved by any one of the following agents: (*a*) cod-liver oil emulsion; (*b*) irradiation with ultra-violet light; (*c*) calcium and parathyroid medication.

There is, I think, a common action to each of these three forms of treatment, and this action may be briefly defined as fixation of calcium. Such a view is supported by the current conception that calcium shortage is the one common factor in all forms of tetany, and it is worth considering whether it is not possible that a true relationship may exist between the twitchings and convulsions of uræmia—which, as we have seen, are associated with a low calcium content of the blood—and the nervous phenomena known as tetany, in which calcium shortage appears to be the outstanding chemical feature. I have indicated that acidosis is usually prominent in uræmia, and we have gone on to note that alkalosis is often very marked in tetany, but that a disorder of calcium metabolism seems to be common to the two states, and that there is (as I think) a close resemblance between the neuro-muscular phenomena seen in the two syndromes, has not always been recognised.

Renal Disease of Gastric Origin.

Having drawn attention to this suggestive similarity, I will now consider for a moment whether there may not occasionally be an even closer association between gastric and renal disease than has usually been recognised. In Table VIII. I have set out some of the

Table VIII.

Progressive Renal Disease.	*Non-malignant Pyloric Obstruction.*
Acid accumulation in blood.	Acid loss from vomiting.

Phosphorus retention.	Chloride loss.
Nitrogen retention.	Nitrogen retention.
Calcium reduction.	Calcium reduction.
Twitchings and convulsions.	Tetany.

outstanding features in: (*a*) cases of advanced renal destruction, and (*b*) cases of pyloric obstruction with tetany. I have already referred to an example from the latter group, and I am indebted to Dr. Hinds Howell for the information that later, whilst under his care in St. Bartholomew's Hospital, before an operation for the relief of her pyloric obstruction, this patient exhibited persistent albuminuria with hyaline and granular casts. Brown, Hartman, Eusterman and Rowntree, and Zeman, Friedman and Mann have reported a series of cases of pyloric or upper intestinal obstruction, usually accompanied by tetany, in which routine histological examination of kidneys removed at autopsy showed entirely unsuspected changes, of a markedly degenerative nature, in the renal tubules. These changes were of the type seen in cases of mercurial poisoning, and Crohn reports the case of a patient who had undergone an operation for pyloric obstruction in whom uræmia, resulting from this renal complication, was the cause of death. I think that this rare group of cases is a very instructive one in reminding us that not only will renal damage produce profound changes in the blood chemistry, but that chemical changes in the blood may themselves exert a destructive effect upon the kidney substance.

Some Experimental Work.

It will perhaps be valuable if we now turn our attention from these purely clinical and biochemical observations to some recent experimental work which seems to me of great importance in connexion with the problems of uræmia. Of particular interest are certain experiments which have been performed in connexion with the rapid ingestion of large quantities of water in animals. In normal circumstances we are protected against a too rapid absorption of water by a series of physiological mechanisms. In the first place, thirst is quickly replaced by satiety, and even if these natural instincts are forcibly overcome the pylorus will by complete closure prevent the entrance of water into the small intestine after a certain amount had been let through. Overloading of the stomach with water is soon followed by vomiting and thus any excess in the small intestine is prevented. It would seem that there is little limit to the speed with which the small intestine can absorb water, but the renal mechanism by which it is removed from the circulation is also a rapidly acting one, and, therefore, provided that the pyloric valve exerts some degree of control it is impossible in ordinary circumstances to produce a true plethora of water in the circulation.

Rowntree and others have, however, by passing tubes through the pylorus in animals, succeeded in introducing water so rapidly into the small intestine that it was absorbed into the blood stream quicker than the animal's kidneys could remove the consequent surplus. A very interesting series of events then occurred, the animals under investigation exhibiting twitchings and strychnine-like convulsions which rapidly passed on to coma and death. It is difficult when reading the accounts of these experiments to find any distinction between the symptoms of such animals and those of patients suffering from renal failure. No one, so far as I know, has dared attempt the reproduction of these experiments on men, but it is worthy of note that in diabetes insipidus a sudden arrest of the polyuria produced by means of the administration of pituitary extract has in some instances been followed by the appearance of giddiness, twitching, and fainting, symptoms which never occur in these circumstances if the intake of water is reduced before the injection of pituitary extract.

The most recent experimental work dealing with uræmia is perhaps less convincing because of its complexity, but close examination shows that it is probably of extreme importance. Working with dogs E. Andrews has shown that when the alkali reserve of the blood is low the injection of salt solution into the circulation fails to produce diuresis. After a short period muscular twitchings appear and from this the animals pass on to a condition in which repeated convulsions terminate in coma, hyperpnœa and death. Examination of the blood of these animals showed definite nitrogen retention, post mortem examination of the animals' brains demonstrated œdema, but the kidneys on microscopic section were found practically normal.

Neglecting for the moment the observations of Andrews on other aspects, it would seem that by these experiments a syndrome indistinguishable from that of uræmia is produced by the injection of sodium chloride solution in the presence of acidosis, without any renal lesion being present before or after. And it is worthy of interest that this worker reaches the conclusion that it is largely owing to the disturbance of calcium metabolism that the convulsive symptoms are produced. In an incomplete, but suggestive series of experiments he has been able to suppress the convulsions of these animals by the intravenous administration of calcium in large doses.

Conclusion.

I have now touched on many of the chemical factors which, at the present stage of our knowledge, appear to be of major importance in the problem of uræmia. That my review must be extremely incomplete I am well aware. And particularly I am conscious of two very important omissions: first, I have made no reference to the relative conditions of the blood and of the cerebro-spinal fluid; and secondly, I have not endeavoured to deal with cerebral œdema as a possible factor in the production of uræmia.

As regards the cerebro-spinal fluid, it is obvious that by studying its chemical state we have better knowledge of the chemical conditions in the central nervous system than if we study the blood alone, but the difficulty of collection is a great handicap in such investigations, and has prevented that frequent repetition of observations which is so easy in the case of the blood. The analyses which were secured on the cerebro-spinal fluid in the case of my patient with cystic disease gave figures similar to those in the blood, as far as we could ascertain, but usually less

marked in degree, there being probably some lag in the appearance of concentrated retention products in the central nervous system; but the impossibility of taking many specimens makes me hesitate to speak more precisely than this. To cerebral œdema I shall refer in a later lecture; for it seems appropriate to discuss this question when dealing with the general problem of œdema.

In the study of medicine we should, said Bright, cultivate a chastened power of generalising our ideas. And if my dissection has dealt with chemical as much as with anatomical peculiarities it is because I feel that it is in that direction that we can most fruitfully pursue our inquiries into the problem of uræmia. Ninety-five years ago, when delivering these very lectures, Bright again and again dwelt on the importance of the chemical aspects of these problems. "If the deranged action of the kidneys," he said, "continue long, the urea can be detected by the chemist's art in the course of the circulation," and in later passages he gave full credit to his friend, Mr. Rees, who was "ardently pursuing the subject of animal chemistry." To-day we are no less dependent on the help of our friends in the laboratories, and I feel it proper to conclude this lecture by expressing my indebtedness to that group of colleagues from whom I have always received such unselfish assistance in the exploration of these difficult problems.

ON THE STATISTICAL EPIDEMIOLOGY OF RESPIRATORY DISEASES.

By HILDA M. WOODS,

ASSISTANT LECTURER IN THE DIVISION OF EPIDEMIOLOGY AND VITAL STATISTICS, LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE.

DEATHS from diseases of the respiratory system form the second largest group of causes of death in this country. The two main headings in this group are bronchitis and pneumonia. This paper considers how these two diseases have varied in time and in place and some of the factors influencing the mortality.

The history of pneumonia dates back to very early times, but the accounts given by some of the ancient writers are not sufficiently clear for identification of the clinical or pathological variety. In his record of diseases at Thasos, Hippocrates[1] found that epidemics of the pulmonary and catarrhal diseases were commoner in the spring of his First Constitution. Pneumonia was often confounded with pleurisy by the old Greek physicians; to Galen, 500 years after Hippocrates, belongs the credit of differentiating them. In the seventeenth century Sydenham gave the first clinical description of broncho-pneumonia,[2] and Morgagni identified the clinical features of pneumonia with solidification of the lungs. At the beginning of the nineteenth century the Bohemian, Carl Rokitansky, defined lobar and lobular pneumonia. According to Ewart[3] the affections of the bronchial system had no separate history before the beginning of the nineteenth century, when Badham, in 1810, introduced the name bronchitis and Laënnec gave his masterly description of bronchitis and pneumonia. But, as we shall see later, the distinction between these two diseases was by no means accurate until quite recent times.

Epidemics of Pneumonia.

The disease has been described in epidemic form from the Middle Ages onwards, and in the opinion of authorities such as Allbutt and Rolleston, the type of disease recorded in these epidemics was more like pneumonia than any other disease. In their "History of Pneumonia" Sturges and Coupland[4] concluded:—

> "We can say no more than that these ancient epidemics resembled generally certain prevalent fevers of later date, in which symptoms of lung mischief occupy a prominent place and death discloses engorgement or consolidation of those organs. The earlier part of the sixteenth century was remarkable for a series of epidemics apt, under certain conditions, to assume this character."

A summary of Hirsch's[5] detailed account of the epidemics of pneumonia in Europe is given below.

The first information on the epidemic prevalence of inflammation of the lungs was in the sixteenth century. Epidemics were recorded in Italy, Germany, the Netherlands, Switzerland, and France, but Italy appears to have been the centre of the epidemics; in fact pneumonia has always been very prevalent in Italy right up to modern times. In the winter and spring of 1601–02 a very severe epidemic of malignant pneumonia prevailed in Italy, and during the seventeenth century outbreaks were recorded in 1610, 1612, 1633, 1696, and 1698. In 1624 there was a severe outbreak in Germany, chiefly affecting children. In Switzerland epidemics were observed in 1652, 1685, and 1695. Opinions were divided as to the contagiousness of the disease; the question of transmissibility in epidemics of pneumonia was raised and debated by many Italian writers in the seventeenth century, but they were unable to come to a decision.

There is ample evidence of epidemics of pneumonia in the eighteenth century, particularly in Italy, Switzerland, and France. The earliest accounts of severe epidemics of pneumonia in the United States and Canada date from the eighteenth century, and the earliest records of malignant epidemics of inflammation of the lungs in England, Spain, and Denmark belong to this period. In France pneumonia was prevalent in pandemic form during the latter half of the century and nearly all the epidemics occurred in the winter and spring. In Spain pneumonia was first described in 1734 and it was widely diffused during the autumn and winter of 1735–36 and 1736–38. In Italy and Switzerland it appears to have been prevalent at intervals throughout the century. For Great Britain we have accounts of the epidemic prevalence of severe forms of pneumonia in Fife in the winter of 1736 and Huxham's account of the outbreaks at Plymouth in the winter and spring of 1733, 1740, and 1746. Of the pneumonia epidemic in 1733 Huxham[6] said that in March "in the beginning of the month the catarrhal fever was everywhere vastly epidemic, which still continues, and now also Squinzies, Pleurisies and Peripneumonies, both of the true and bastard kind are frequent." In April he noted: "the epidemic fever is still up and down the country and many are now in a consumptive way from the ill-effects of it and an unfavourable crisis: Many are seized with Pleurisies and Peripneumonies." In the records of nearly all the epidemics in Europe during the eighteenth century attention is drawn to the malignant type of the disease and its so-called typhoid symptom.

Early in the nineteenth century rather more definite views were held about the term "pneumonia" after Laënnec had given a clear definition of the two diseases bronchitis and pneumonia. Our records of deaths from these two causes in England and Wales show that there was much interchange of certification between pneumonia and bronchitis, and we cannot study the statistics of the two diseases separately—at any rate not for the nineteenth century. Stevenson[7]

showed this quite definitely in his analysis in the decennial supplement 1901–10. He considered that—

"Comparison of the mortality returns from the two causes at different times leaves no doubt that the bronchitis of to-day may be the pneumonia of to-morrow, and vice versa, though the main change in the period covered by Table 10 (1861–1910) has been one from bronchitis to pneumonia."

He examined the death-rates for different periods of life from 1901–10 back to 1861–70, and, broadly speaking, he found that the changes which have occurred in the recorded mortality from pneumonia and bronchitis are largely attributable to transfer between the two diseases, partly because of the fact that the extreme reduction of bronchitis mortality is so nicely balanced at each age by just the rise in pneumonia mortality required to reduce the decline from the two causes to moderate dimensions. There is just one exception, and that is at ages 15–25 in the case of males, where the rise in pneumonia mortality is unbalanced by a fall in bronchitis mortality. Two epidemics of pneumonia in the nineteenth century were the subject of special reports to the Local Government Board. One was reported by Ballard [8] at Middlesbrough in 1888, when 1633 persons were attacked in a population of 97,000 and there were 369 deaths. The second report by Parsons [9] was on the epidemic at Scotter in Lincolnshire in 1890.

The standardised rate of mortality from bronchitis and pneumonia from 1861–1911, given in decennial periods in the Registrar-General's decennial abstracts, shows that the combined mortality from these two diseases for males increased rapidly between 1861 and 1880, then more slowly to a maximum in 1881–90, followed by a decline in 1891–1900 and a big drop in 1901–10.

Standardised Death-rates per Million Living.

Year.	Males.	Females.
1861–70	2923	2436
1871–80	3415	2815
1881–90	3433	2778
1891–1900	3342	2693
1901–10	2679	2142

The maximum mortality for females was reached in 1871–80. It should be noted that the rules of certification of the deaths discussed here only include those in which pneumonia or bronchitis was alone recorded on the certificate or associated with another cause of which they take precedence under the rules of tabulation. Under the revised rules of 1901 pneumonia was given priority over local diseases, and this doubtless increased the number of deaths tabulated under pneumonia. Under the present rules certificates returning measles and broncho-pneumonia would be tabulated under measles and those recording influenza and pneumonia under influenza.

Climatic Conditions and Pneumonia.

The increase in mortality from bronchitis and pneumonia during the middle of the nineteenth century was frequently commented on by Farr. He thought that much of it was due to the dust and smoke of cities, and in 1869 he asked whether factories and kitchens could not largely consume their own smoke—a question which has been frequently asked since. He also spoke of the risk from atmospheric temperature and compared the annual deaths from respiratory diseases by month in London with degrees of temperature. He concluded that the fatality from these diseases was directly influenced by cold weather. The question of the relation between unfavourable climatic conditions and the death-rate from respiratory diseases is discussed and various conjectures are made in almost every report on pneumonia and bronchitis. The seasonal curve of mortality is well known. Fig. 1, which is copied from the Registrar-General's annual report for 1925, shows the mean annual death-rate from respiratory diseases for 1921–25 plotted against the mean monthly temperature for these years. In order to compare the two curves the temperature scale has been inverted. The curves are very similar: the winter rise in mortality from respiratory diseases corresponds to the fall in temperature, and with the rise in temperature in the spring there is a decline in the respiratory death-rate. But the month of maximum mortality is not in the depth of winter, the coldest months of the year, but in February, the time of greater variation. Probably the most valuable recent work on the subject of climatic conditions and mortality is that of Huntingdon,[10] who thinks that a variable climate is that most productive of health and efficiency; he has collected data to prove that the ideal climate is that enjoyed by the inhabitants of England and Wales. One wonders whether he would consider the climate we have experienced during 1927 as an ideal one. Perhaps we are really no worse off now than 200 years ago; for example, this is Huxham's [6] monthly report of the weather in 1734.

June.—An easterly wind blew almost daily from the 6th to the 20th.

July.—Fair but cold at beginning of month, middle of month south-west wind with rain, then north wind returned. Later an immense quantity of rain fell.

August.—Fair at beginning, but about middle of August very much rain and too much also at the end of it.

This would not be a bad account of the weather for the same months of 1927.

Temperature and the Pneumonia Mortality-rate.

We will consider first the quantitative relation between temperature changes and the mortality-rate from pneumonia. The Medical Statistical Staff of the Ministry of Health investigated this point in some detail and tried to estimate how many deaths might be expected on the average with changes of temperature. Most of the work was done for the report on Influenza of the Ministry of Health, and those who are interested in the relation of weather and epidemic disease should read Chapter VII. of the report. The doctrines of Hippocrates, Galen, Sydenham, and others are set out and some of their arguments are discussed.

The data used were confined to the registration districts of London and to the periods 1850–89 inclusive, because no records could be found of air temperature for any other large town in England for many years. The period was limited to 1850–89 because there were no influenza epidemics during this period; since 1890 there have been several epidemics, which would have affected the pneumonia death-rate. The death-rate from all forms of pneumonia in each of the first 12 weeks of the year was computed for the 40 years and correlated with the mean temperature of the air in the preceding week—i.e., a correlation table was formed from the 480 pairs of observations and 2° was taken as the unit of grouping for temperature and 4 per million for the death-rates. The correlation was quite significant—$-\cdot371 \pm \cdot026$. From the regression equation it was calculated that a drop of 1° Fahrenheit in the temperature corresponded to a rise in the pneumonia death-rate of the next week of about 6 per 10 million living. The calculation was repeated for the last 12 weeks of each year from 1850–89 and also for the years 1903–14 (135 observations). The correlation between pneumonia and temperature for the fourth quarter of the years 1850–89 was $-\cdot458 \pm \cdot024$. Now we come to the interesting result that in the recent period, 1903–14 the correlation between the pneumonia death-rate and the temperature of the previous week was much higher than in the pre-influenzal period 1850–89. This time the correlation was $-\cdot707 \pm \cdot029$. Regression lines were fitted to the data and the slope of the line for the last period was much steeper than for the earlier period—a greater difference than could be expected from chance fluctuation.

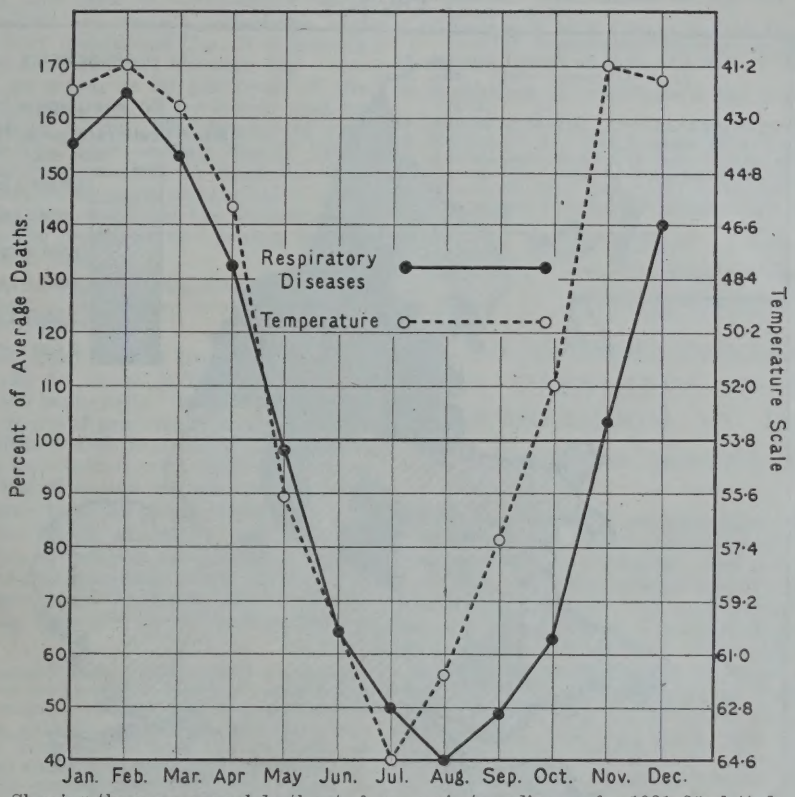
The absolute magnitude of variations of death-rate with temperature is not large and the irregularity of the trend is considerable, but it looks as though the pneumonia of recent years has varied more closely with temperature changes than in the earlier periods. No correction was made for trend in this first analysis. For the next stage of the inquiry deaths from bronchitis and pneumonia were combined and allowance was made for seasonal variation, by referring every death-rate and every temperature in each week of the 52 weeks of the years to the mean rate of mortality and the mean temperature of the week of the year to which it belonged—that is, deviations of mortality from their

norms were correlated with deviations of temperature from their norms.

For example, suppose that for the 40 years of the series the mean death-rate from the respiratory diseases in the third week of the year was 109 per million, and the death-rate in one particular third week was 93 per million, the difference between 93 and 109 is −16, then −16 was entered in the correlation table against the corresponding difference between the temperature and its mean for the same week for the 40 years. Following this method throughout for all the weeks of the 40 years one had 2087 observations. Now one proceeded to try to answer the following questions: What is the relation between temperature of the week and the respiratory death-rate for the same week, temperature of one week and the respiratory death-rate of the next week or the week a fortnight later? These were the correlations: temperature and death-rate of the same week −·231±·014; temperature and death-rate of the next week −·477±·011; and temperature with death-rate of fortnight later −·405±·012.

The closest relation is therefore between the death-rate and the temperature of the previous week. The regression equations showed that a drop of one degree of air temperature below the mean temperature of the week was associated on the average with an increase of 2·5 deaths per million living above the normal average of the following week's mortality. But the relation was not sufficiently stringent to be of any real value in prediction. The conclusions from these investigations were that if the temperature falls below the normal of the season of the year, on the average, the arithmetical increase of mortality will be 2·5 per million living, but so many other known and unknown factors are involved in any particular week that the actual result may depart considerably from its average value.

FIG. 1.



Showing the mean annual death-rate from respiratory diseases for 1921–25 plotted against the mean monthly temperature for these years. Copied from the Registrar-General's annual report for 1925.

Fog and Respiratory Mortality.

Fog has been frequently spoken of as an important factor in respiratory mortality. Leonard Hill has emphasised the evil influence of smoke and fog upon health, partly because of the obstruction of sunlight. In 1925 the medical officer of health for Glasgow [11] attributed the increase in the respiratory death-rate during November to the fog which prevailed during the month, and which became dense during the four days Nov. 18th–21st. He reported that—

"During the four weeks ending Nov. 28th, 1468 deaths were registered as compared with 1224 for the same period last year. This increase referred almost entirely to the last two weeks of the month—i.e., during the fog week and that following—when the death-rates became 18·7 and 21·0 respectively, against 15·6 and 16·6 for the same weeks of last year. The number of deaths of children under 5 years of age was practically unaffected, the increase in the mortality over last year being largely confined to those over 60 years of age. The fog thus affected principally older people. It will also be noted that the mean temperature before and during the period of fog was low—35·8°, 36·3°, and 36·1° for the three weeks ending Nov. 28th."

He goes on to say that this appears to indicate that when fog is associated with low temperature the respiratory death-rate among older people is influenced very considerably, although its effect is not evident in the case of children. But if we try to obtain a precise numerical evaluation of the bad effects of smoke and dust, there are very serious difficulties. We cannot definitely show that a rise in mortality is the direct action of fog, any more than we can demonstrate the absolute influence of temperature on the death-rate. Russell's [12] investigations are the only ones in which an attempt has been made to put the relation of fog on a quantitative basis. He shows that the numerical measure of fogginess is by no means a satisfactory one. He examined the influence of fog and temperature on the weekly mortality from respiratory diseases among children and adults during the winter months in two metropolitan boroughs—Islington and St. Pancras—over a period of 21 years. His conclusions were that fog itself has no appreciable effect on the death-rate, but if fog is associated with a low temperature and frost the respiratory death-rate of adults can be influenced very considerably, but there is not much effect on the mortality of young children. He gives, as illustrations, the experience of the two London boroughs between October and March in 1883–84 and 1892–93. In both periods there were considerable outbursts of fog in November and December, the fog records of the two periods being not dissimilar. But in 1883 there was no obvious increase of mortality after the fogs. In 1892 there was a large increase, and in that year the fog was associated with a sharp fall of temperature not occurring in 1884. His conclusions to his second report sum up very clearly the relative importance of fog and temperature:—

"It is essential to bear in mind that, in any study of the influence of weather on the prevalence of disease, the assignment of the increased mortality to any particular factor is not nearly so simple as is generally believed. The fact, often overlooked, is that there are a multiplicity of causes, both atmospheric and meteorological, all of which are highly inter-related, and it is the cumulative effect of these, and not the influence of an individual factor, that finds expression in an increased death-rate from respiratory disease."

The same point is strongly emphasised by Sir George Newman [13] in the following sentence :—

"The true inference is, I believe, that in the matter of atmospheric pollution, as in that of meteorological factors, the inter-related variables in any given case are so numerous that only by means of a far longer series of observations than our data provide can any valuable statistical conclusions be reached."

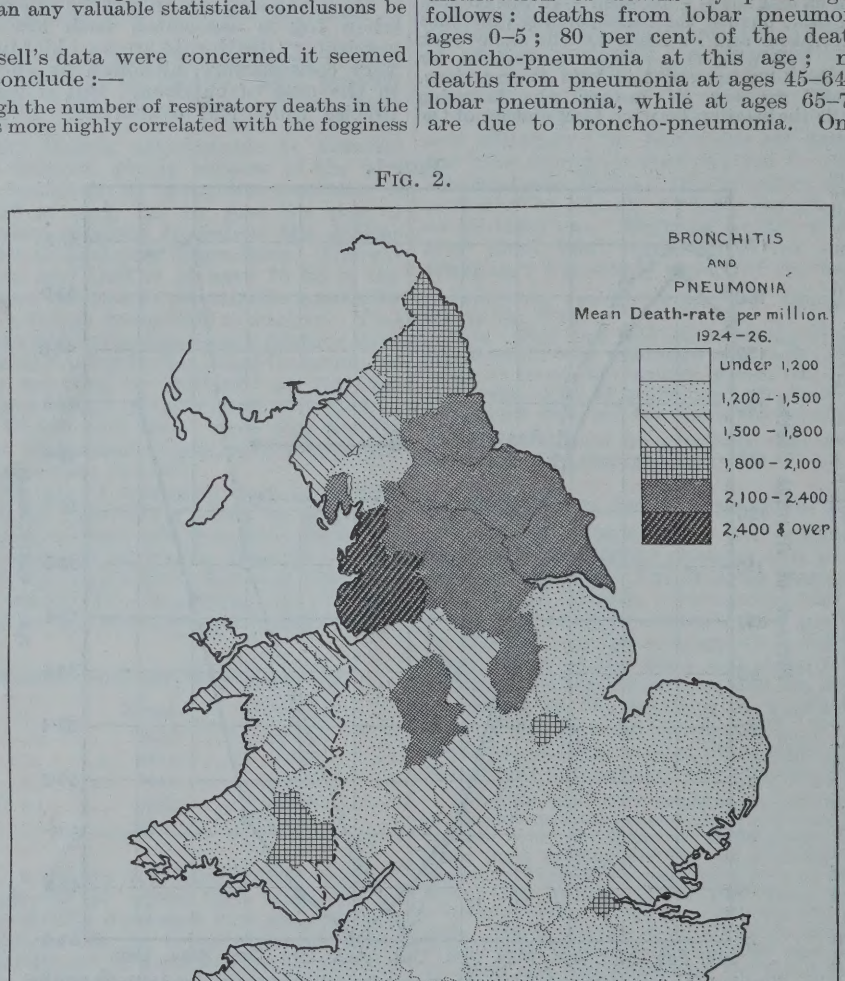
So far as Russell's data were concerned it seemed warrantable to conclude :—

"1. That although the number of respiratory deaths in the following week was more highly correlated with the fogginess than with the temperature of the previous week over certain periods, yet, on the average, a low temperature exercised the greater influence.

"2. That knowing the temperature and the amount of fog, it is possible to predict the mortality of the succeeding week, but only within a marginal error of roughly 30 per cent."

Thus in atmospheric pollution as in meteorological factors the number of inter-related variables are so numerous that we cannot measure the influence of any one factor with any certainty, but as Sir George Newman [13] pointed out, all the statistical evidence points to sharp changes of temperature, particularly in their effect upon the aged, as the real basis of the evil reputation of climate in relation to respiratory disease.

FIG. 2.



Map showing the relative distribution of mortality from bronchitis and pneumonia, 1924–26.

The Age Factor.

It is very important to study the influence of external factors on the mortality from respiratory diseases at different age-periods, as Russell has done. From various investigations that have been made it is quite clear that such factors as social and climatic conditions as far as we can measure them do vary considerably in their fatal effect on mortality at different ages. Young [14] found that meteorological factors had very little influence on the mortality of children under 5. The present writer [15] made a similar analysis and found a definite association between temperature and mortality at ages 40–60 and 60–80, that the lower the temperature the greater the mortality from pneumonia at these ages. I found also that environmental conditions were an important factor of the mortality among children under 5, whereas these factors were of much less importance in middle life and of little or no importance in later life.

A feature of pneumonia and bronchitis is that they are extremely fatal at both extremes of life. The distribution of deaths by pathological type is as follows: deaths from lobar pneumonia are rare at ages 0–5; 80 per cent. of the deaths are due to broncho-pneumonia at this age; nearly half the deaths from pneumonia at ages 45–64 are ascribed to lobar pneumonia, while at ages 65–74 more deaths are due to broncho-pneumonia. One of the most interesting epidemiological features of the mortality from respiratory diseases in England and Wales is the variation of the mortality in the different areas. In 1926 the rate of mortality from pneumonia varied from 486 per million in the rural districts of the south to 1169 in the county boroughs of the north. In 1913 Stevenson commented on the striking differences in the mortality in the following terms :—

"Apart from London, where it is fairly high, the mortality steadily decreases from north to south in all classes of area and in both sexes, the position of Wales being generally intermediate between the North and the Midlands. The range of mortality is extreme, being almost four times as great for males in the county boroughs of the north as for females in the rural districts of the south and three times as great when males alone are compared. Even when comparison is restricted to the same class of area in each case the mortality of the north is in no instance very much less than twice that of the south. No doubt this depends to some extent upon industrial conditions, but these can scarcely explain the great difference between the North and the Midlands. Evidently pneumonia is to a large extent a preventable disease, and the north of England has still much to learn with regard to its prevention. It is a striking fact that all these statements as to relative mortality copied verbatim from the Report for 1912 apply equally to the year 1913."

The mortality from bronchitis and pneumonia in 1926, as compared with that in 1913, was much lower, but the remarks as to the relative distribution in the country are still valid (see map, Fig. 2). The statistics of notifications of pneumonia also point to the unsatisfactory position in the north, particularly

ıe north-west of the country—in Lancashire and ıeshire. The excessive mortality from pneumonia in ıe north of England might be attributed to the ırsher climate, but the great variation between the ortality in separate districts of the north makes evident that climate is not the whole explanation. reenwood [16] showed that, although economically ıe working-class families of Bolton and Warrington ere better off than the Reading families, the rate of ortality from all causes was far higher in Bolton ıd Warrington than in Reading. The chief dis-epancy in the adult mortality was with respect to ıeumonia. Industrial conditions in the north are obably the explanation, because of the evil effect dust and smoke and lack of ultra-violet rays. ıncashire and Cheshire are mainly industrial, and ith the present factory conditions the air is heavily olluted with smoke and dust all through the year. ill estimated that as much as 50 per cent. of the ınlight in Manchester was cut off by smoke and no ss than 40 per cent. in Leeds. The deposit of soot Manchester [17] for the year ending March, 1922, as 480 tons and as much as 697 in Rochdale; in alvern there was only 69 tons during the same year. obably the best known work on the influence of ısty occupation on the health of the worker is that Collis, who considers that—

"Dust which impairs the vitality of the lungs predisposes tuberculous infection . . . and at the same time predis-ses to other respiratory diseases."

He has shown that dust formed from the husk of getable fibres tends to cause a typical form of thma associated with bronchitis. Bronchitis follows on inhalation in excess of practically every form of ıst which is insoluble and non-colloidal. Pneu-onia, although its association with dust inhalation not as marked as that of bronchitis, may result from halation of the same dusts as cause bronchitis.

It would take too much space to go into the tails of the various investigations Collis has made, ıt these are some of his general conclusions given in report [18]: "The General and Occupational Prevalence Bronchitis and its Relation to other Respiratory iseases":—

For coal miners generally the bronchitis and pneumonia tes are high, with the exception of Northumberland and arham, while men working on the coal face experience gher mortalities from phthisis, pneumonia, and bronchtis an do other miners. Exposure to heat and fumes seems have a definitely bad effect with regard to bronchitis and similar, although less pronounced effect with regard to ıeumonia. Bronchitis and pneumonia are high among tton operatives and rope makers and especially high among tton strippers. Woollen workers, carpet makers, millers, ıd carpenters, on the other hand, show no excess of either onchtis or pneumonia. Occupations in which there is posure to silica dust, such as potters, cutters, sandstone, ıd tin miners, all show a high mortality from respiratory seases. All these results are based on the rates of ortality for males at working ages 25–64 and therefore do ot include the old-age mortality.

Since cotton manufacture is a great north-western dustry, the high rates of mortality from bronchitis ıd pneumonia in that area suggest that the workshop nditions are to a large extent responsible. The fact ıe cannot get away from in studying respiratory seases is that so much of the mortality is preventable, ıd the industrial towns of the north have still very uch to learn with regard to its prevention.

No one will dispute that skilful nursing is the sential treatment. In London during 1920 only 8 per cent. of 5315 deaths from pneumonia occurred hospital and nursing homes, and 22 per cent. in oor-law institutions. As many as 60 per cent. of ıe deaths occurred outside these institutions—in her words, at home. In a recent report by the inistry of Health on Scarlet Fever and in the annual port of the Chief Medical Officer for 1923 it was ated that—

"The time has come when the whole question of using olation hospitals to greater advantage calls for the con-deration of local authorities, and it may well be that fuller regard should be paid to patients suffering from respiratory diseases."

If greater provision were available in hospitals for the treatment of respiratory diseases much of the mortality might be reduced.

AN IMPROVED TECHNIQUE FOR THE TREATMENT OF INTERNAL HÆMORRHOIDS BY INJECTION.

BY ARTHUR S. MORLEY, F.R.C.S. ENG.

THE treatment of internal hæmorrhoids by means of injection has been making steady strides since the attention of the profession was forcibly attracted to it in 1914. It is becoming known to an ever-increasing number of medical men and to the lay public. In the first paper which I published on the subject [1] in 1916, and in my book on Hæmorrhoids,[2] I described a method of treatment by injection of a 20 per cent. solution of phenol in equal parts of glycerine and water, in this respect following the practice of most of those who had previously practised treatment by injection. This solution was injected into the centre of the pile-mass. Some other surgeons, and notably Dr. Dudley Wright, used a 10 per cent. solution of carbolic in the same way.

Since 1914 I have treated not less than 5000 cases of hæmorrhoids in this way, and the results have been extremely satisfactory on the whole, both to the patients and to myself. I am still in touch with a good many patients whom I treated in 1914 and 1915, and I hear of a great many more through friends whom they recommend to consult me.

My peace of mind has been disturbed from time to time, however, by certain complications which have occurred. The chief of these was severe pain, coming on some 48 hours after an injection, and usually due to sloughing of part of the pile-mass. This sloughing occurred only in about 1 in every 200 cases, but it led to really intense pain, which frequently lasted for more than a week. In other cases—some attended with this sort of pain and some without it—rather alarming secondary hæmorrhage took place. This complication occurred, according to calculations from statistics of my own cases, in about 0·25 per cent. of cases. It was due to slight sloughing opening up a blood-vessel of appreciable size. I have never met with a fatal case of hæmorrhage after injection, but in several cases the bleeding was sufficiently severe to be very alarming and to leave the patients debilitated. As a great many of my patients come to me from all

[1] THE LANCET, 1916, i., 617.

[2] Hæmorrhoids, their Ætiology, Prophylaxis and Treatment by Means of Injections. London: Henry Frowde, Hodder and Stoughton.

parts of the country and are out of reach in case of the necessity for prompt attention, the possibility of these complications, even in so small a proportion of cases as 1 in 200, troubled my mind considerably. Moreover, their occurrence did the method considerable harm, because the patients in whom they occurred and the medical men who were called in to deal with them naturally did not realise that complications are the exception and not the rule.

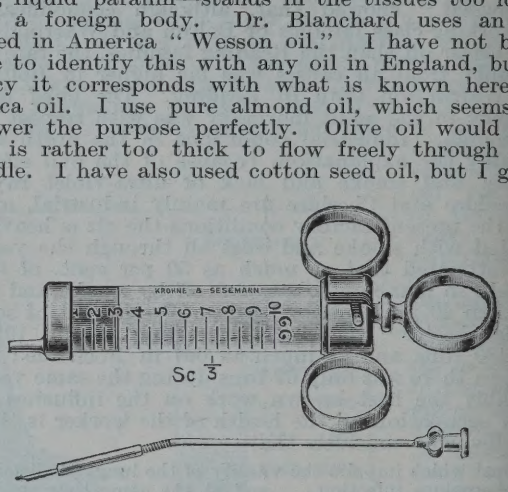
I first considered the advisability of using a weaker solution of carbolic; but I had met many patients who had been relieved promptly of all their symptoms by an injection of 20 per cent. carbolic, after other surgeons had failed to give them relief with more than the usual number of injections of 10 per cent. solution; and, moreover, although still more rarely, the same complications did occasionally arise even with the weaker phenol.

Improved American Technique.

This was the position at the end of 1926. At about that time it came to my knowledge that a different technique was being employed by proctologists in the United States, notably one which had been used very largely by the late Dr. J. D. Albright, of Philadelphia, and by Dr. C. E. Blanchard, of Youngstown, Ohio. I communicated with the latter surgeon, and he very kindly sent me various papers and a copy of his book,[3] in which the American technique is described in detail. Since early in 1927 I have been using this new method almost entirely, and, whilst the ordinary symptoms of internal hæmorrhoids—bleeding and prolapse in particular—have disappeared with the same certainty after the first one or two injections, the occurrence of severe pain and of secondary hæmorrhage has entirely ceased to worry me. In a letter which Dr. Blanchard was good enough to write to me in 1926, he remarks, "... you in England are about where we were in 1912—annoyed by troublesome complications, pain slough, &c. I have called this our grey-hair-making days." From the experience I have had of the improved technique, I am so much impressed by the absence of troublesome complications that I do not think that Dr. Blanchard's picturesque description is altogether beside the mark.

The chief differences between the two methods are that in the older one a few drops of a 20 per cent. solution of carbolic were injected right into the centre of the pile-mass, the solution being in water and glycerine; in the improved method a large quantity (some 1 to 3 c.cm.) is injected *submucously*, carefully avoiding entering the needle deeply and any risk of penetrating large vessels. The syringes which I used for injecting the 20 per cent. carbolic solution are far too small for the new method, and one holding about 10 c.cm. is necessary. Dr. Blanchard uses a gold needle fixed on a long straight stem, and provided with an adjustable screw guard, which can be set so as to allow the desired length of needle to be exposed. I have modified Dr. Blanchard's pattern of syringe, and have had one made by Messrs. Krohne and Sesemann, of Duke-street, W. 1, to my own pattern. This syringe is an ordinary 10 c.cm. "Record" syringe, with an eccentric nozzle. The barrel may be made of glass, if preferred, but glass barrels are liable to frequent breakage through boiling, so I now use a metal barrel, and there is nothing to break or to get out of order. I use a gold needle similar to Dr. Blanchard's, but with the stem bent to an "elbow" just above the guard. This keeps the point of the needle, when in use, always in view, and renders the injection very much easier than with a straight shaft. Since the syringe is a "Record," the shaft of the needle plugs on without any screw or washer, but the fit must be very good in order to obviate any risk of the syringe and shaft of the needle parting company whilst the injection is being made. The guard is not essential, but it prevents any chance of the needle being inadvertently introduced further than is intended. The gold needle does not rust nor wear out, and is easily sharpened.

The solution recommended by Dr. Blanchard is a 5 per cent. solution of phenol in any *vegetable* oil. Animal oil is absorbed too rapidly, and mineral oil—e.g., liquid paraffin—stands in the tissues too long like a foreign body. Dr. Blanchard uses an oil called in America "Wesson oil." I have not been able to identify this with any oil in England, but I fancy it corresponds with what is known here as Lucca oil. I use pure almond oil, which seems to answer the purpose perfectly. Olive oil would do but is rather too thick to flow freely through the needle. I have also used cotton seed oil, but I gave



A modified "Record" syringe and gold needle.

it up because in some patients it seemed to produce temporary headache and malaise, which do not occur when almond oil is used. If many cases are to be treated it is convenient to keep a 25 per cent. stock solution of carbolic in the oil. Pure phenol crystals should be used, and liquefied over a water bath; 1 part of the liquefied crystals to 3 parts of pure almond oil make a 25 per cent. solution. To this solution 10 grains per ounce of menthol crystals may be added. This addition was recommended by the late Dr. Albright, who regarded it as an analgesic and thought that it prevented nausea. It seems a little doubtful whether it is necessary, but I have not tried the oil without it, so I cannot speak from experience. To make up the "working solution," all that is necessary is to add 1 part of the stock solution to 4 parts of almond oil. This makes a 5 per cent. solution, of which it is convenient to prepare from 4 to 8 oz. at a time, which is sufficient, as a rule, for some 20 cases. I label my 5 per cent. solution "P-O 5 per cent." (phenol oil 5 per cent.). It keeps indefinitely, and, in consequence of the presence of phenol, it is always aseptic. I also keep a 10 per cent. solution ready prepared, but I very rarely use it, reserving it only for cases in which there is an exceptionally great tendency to hæmorrhage, which does not yield, as usual, to the first one or two injections.

Technique.

Dr. Blanchard works through a speculum known as Brinkerhoff's speculum, which is very long and tapering, rather like Mummery's speculum, but very much longer and with a slide over the fenestra. I do not like this instrument, because only one pile at a time can be seen through it, and it is therefore difficult to get a clear view of the parts. I find a Kelly's speculum, such as I have described elsewhere (loc. cit.), the handiest instrument for the purpose.

At the first treatment the injection should be made high up, at the extreme upper end of the hæmorrhoid, and for this purpose it is often necessary to go almost as high as the lowermost Houston's valve. It is for this reason that the long shaft to the needle is necessary. The needle should be inserted just under the mucous membrane so that the oil is injected into the submucous coat. On no account should any attempt be made to inject it into the centre of the pile-mass or into the vascular plexus in the middle of the pile. The injection is made slowly. No directions can be given as to the precise quantity to inject. When enough has been used, the pile can be seen swollen and whitened, and the precise point at which to stop is the moment when the superficial vessels can be seen as very fine red thread

[3] An Epitome of Ambulant Proctology. By Chas. Elton Blanchard. Medical Success Press, Youngstown, Ohio.

nning over the surface of the whitened hæmorrhoid. his is what Dr. Blanchard calls his "striation sign," and is the guide to the ideal amount of fluid to inject. A w drops more or less are of no great importance, however, d it is only by experience and judgment that the correct gree of distension of the hæmorrhoid can be gauged. very pile is dealt with similarly at each sitting. At subquent sittings one works lower until one reaches the oximity of the muco-cutaneous junction. Great care ust be exercised not to encroach upon this, or pain will evitably follow. For the same reason care must be taken ot to inject a great excess of fluid into any pile, because ie solution is apt to gravitate downwards, and, if the eatment is pressed too vigorously, the oil may find its way nder the skin and cause pain.

The interval between the injections may be from ve to seven days. Usually five injections at these tervals are required. As with the older method, ie symptoms almost invariably disappear from the oment of the first injection, and at the second sit the patient usually greets the surgeon with some ich remark as, "Marvellous, you are a perfect izard!" So rapid and absolute is the relief of mptoms that, as in the case of the 1 in 20 carbolic lution, a frequent difficulty is to persuade the tient that further injections are really necessary. sufficient injections are not given, however, the mptoms are likely to recur after a few months of mfort. During the summer of last year I was vay for six weeks, and on my return I resumed the terrupted treatment of a great many cases. Those ho had had only one injection before I left London ad remained comfortable, but symptoms were just ginning to reappear in several patients, and in all them the piles were larger than I am accustomed find in patients who have had a similar number of jections without any break. It is not as easy with is method as with the older one to decide exactly hen enough treatment has been given, because the l remains standing under the mucous membrane r a considerable time, and its pressure leads to nsiderable inflammatory thickening and consenent hardening of the piles. After about five injecons, however, the piles have diminished very nsibly in size, and, if their remains are of parchmentke hardness from their upper limit down to the mucotaneous junction, it is safe to consider that treatent has been sufficient. Here, again, it is difficult lay down precise directions in words; it is largely matter of experience at what precise point to stop eatment with confidence that recurrence is very probable. It is better to give one or two more jections than to let the patient go on his way joicing before he has really had enough.

The Pathological Effects.

The pathological effects of this method require rking out more fully. As far as I can see, the oil mains unabsorbed for a considerable time and ts up an aseptic inflammatory reaction between e mucous and muscular coats of the rectum with bsequent formation of dense scar tissue, which nds these coats closely together. The oil, whilst ll standing in position and distending the mucous embrane, keeps up a very considerable degree of essure on the vessels in the pile-mass, and the ar tissue which forms at a later stage must tend its contraction to obliterate any vessels which ve escaped the effects of the pressure by the oil elf. If the needle is inserted properly, only just neath the mucous membrane, no oil can get into y macroscopic vessel, and I have never seen nor ard of any trouble from oil finding its way into the culation. Nor is there ever any trouble from morrhage at the time of the injection, such as d to happen occasionally when the solution was liberately introduced right into the centre of the e-mass. Indeed, hardly a drop of blood escapes ring the injection—no more than after ordinary podermic or submucous injections.

Symptoms of carbolic acid poisoning might be pected, but I have never seen any, and I have never ind carboluria or other sign of carbolic acid absorption. The explanation is that the oil is absorbed extremely slowly; it has not disappeared from the sites of injection at the end of a week. In a few cases, where rather more of the oil than usual was used, there has been giddiness and "muzziness" when the patient gets off the couch. This has always passed off in 15 minutes, and is probably due rather to the menthol than to the phenol. In the very few cases in which I have used a 10 per cent. solution instead of the usual 5 per cent. there has been some pain and aching, and some of the patients have complained of feverishness and malaise. Whether these symptoms can be considered as mild symptoms of carbolic acid poisoning I do not know.

Complications seem to be rather like "snakes in Ireland"—they do not exist, beyond the very trivial ones referred to above. There is usually a certain amount of aching, which comes on about an hour after an injection and lasts for three or four hours. It is easily relieved by aspirin, phenalgin, or other drug of that type, and few patients complain much. If one has injected considerably more of the solution than is prudent, a little surface ulceration may occur, but I have not seen any real sloughing since I have used the new solution.

The treatment is suitable to all cases of internal hæmorrhoids, although where there are complications, such as fissure or strangulated irreducible piles, preliminary treatment by divulsion of the sphincter may be necessary.

Summary.

1. Use a 5 per cent. solution of phenol in vegetable (e.g., almond) oil. 2. Inject the solution under the mucous membrane and not into the pile-mass. 3. The quantity injected into each pile is usually from 1 to 2 c.cm., using Blanchard's "striation sign" as a guide. 4. If the injection is properly made, no bleeding follows with the withdrawal of the needle. 5. Continue the injections at intervals of from five to seven days until each pile is of parchment-like hardness from its upper extremity to the muco-cutaneous junction. 6. The use of 5 per cent. phenol in oil eliminates the occasional unpleasant complications which marred to a slight extent the use of 20 per cent. phenol in glycerine solutions.

The method is one which requires special instruments and very special skill and experience, and I do not think it is one to be attempted by those who only have few opportunities for its employment. But I strongly recommend it to rectal surgeons who have been accustomed to use the older injection methods; I feel sure that, when once they have acquired the necessary technique and experience, they will adopt it exclusively. Apart from an occasional complicated case, where a preliminary divulsion is necessary, its use can entirely supersede operations of the old sort, with their attendant anæsthetics, confinement to bed, absence from work, pain and dread.

I cannot conclude this article without expressing my gratitude to Dr. Blanchard for giving me so much useful information and for details of his own technique and much invaluable advice.

WORKMEN'S CONTRIBUTIONS TO A HOSPITAL.—Contributions of a penny a week from workmen, amounting to £2500, formed more than half the total income of Workington Infirmary last year. After setting aside £1000 for investment, the institution was able to carry forward £682.

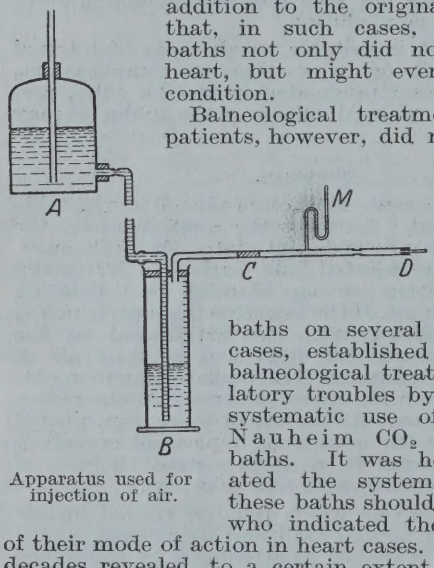
MENTAL DISORDER IN SCOTLAND.—At the annual meeting of the Royal Edinburgh Hospital for Mental and Nervous Disorders, Edinburgh (formerly the Royal Edinburgh Hospital for the Insane), Prof. G. M. Robertson, physician-superintendent, stated that nearly two-thirds of those who go for treatment do so voluntarily. The certified population of the hospital is diminishing, and he was satisfied that the day of the "certified lunatic" was drawing to a close in Scotland.

CARBON DIOXIDE THERMO-SALINE SPRINGS IN THE LIGHT OF MODERN RESEARCH.*

By ADOLF SCHOTT, M.D.
(BAD NAUHEIM.)

IT would be carrying coals to Newcastle to emphasise here the importance of physiotherapy in the treatment of heart disease, Great Britain being the country where physical treatment for an affection of the heart was recommended for the first time. It was Stokes who, in the middle of the last century, advised exercise as a method of treatment for patients suffering from "fatty heart." Baths, however, of all kinds were even then strictly contra-indicated for any heart patient, until Beneke modified the general medical opinion. Beneke showed that the Nauheim baths, then used for the treatment of rheumatism, skin diseases, &c., could also be applied in those cases where the patients suffered from a chronic affection of the heart in addition to the original disease, and that, in such cases, the Nauheim baths not only did no harm to the heart, but might even improve its condition.

FIG. 1.



Apparatus used for injection of air.

Balneological treatment of heart patients, however, did not exist until August Schott, as the result of his observations on the effect of the natural Nauheim baths on several hundred heart cases, established in 1880 the balneological treatment of circulatory troubles by means of the systematic use of the natural Nauheim CO_2 thermo-saline baths. It was he who elaborated the system upon which these baths should be given, and who indicated the main points of their mode of action in heart cases. The following decades revealed, to a certain extent, the scientific basis for this then new and purely empirical method of treatment, and a great number of details as to the mode of action of these baths on the circulation were shown by the extensive clinical and research work of Th. Schott, Strasburger, Jacob, Müller and their various co-workers, Ernst Weber, Hediger, and many others in different countries.

As the result of this work, the tonic effect of the natural Nauheim CO_2 thermo-saline baths on circulation and respiration was demonstrated, as well as the superiority of the natural baths compared with artificial ones. The Nauheim baths forming a stimulus of the most complicated kind, influencing circulation and respiration from the skin, I decided to obtain a more intimate view from another point as to the mode of action of these baths by studying their effect on the subcutaneous CO_2 and O_2 tension, these tensions being dependent on the conditions of circulation and respiration. The study of the subcutaneous gas tensions seemed to be of still greater interest than blood gas examinations, as the investigation of subcutaneous gas tensions brings us a step nearer to the tissue cell itself.

The possibility of studying subcutaneous gas tensions easily and accurately has been given to us by the ingenious method of Campbell who showed that after the injection of N_2 or air into the subcutaneous tissue spaces, an equilibrium of tension is established between the injected gas and the tissues.

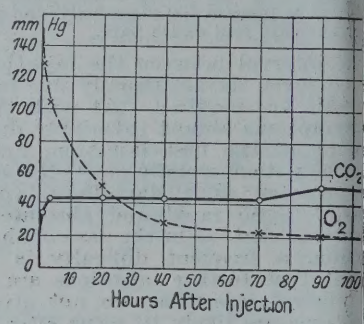
* Read before the Section of Balneology and Climatology of Royal Society of Medicine on Jan. 26th, 1928.

This equilibrium being attained the CO_2 and tensions remain approximately constant for a lo time, so that ready means are afforded of studyi the influence of exogenous factors on tissue C and O_2 tension.

Following, on the whole, the technique as elaborat by Campbell I developed a method of my own injecting air into the subcutaneous tissue spac This enabled me to perform the injection steadily a without difficulty at any speed and pressure required. The simple technique is as follows (Fig. 1):

Water is run from a Mariotte flask (A) thereby displacing air from a graduated cylinder (B) through a filter of cotton-wool (C) into a rubber tube which leads to the injection needle (D), prepared according to Campbell's instructions so that there is a minimum of dead space on withdrawal of the samples from the subcutaneous tissue spaces afterwar By observing the bubbles in the Mariotte flask, manometer (M) connected with the rubber tube, and level of the water in the cylinder, a steady injection o known quantity of air under known pressure can easily assured, the water flow being regulated by a screw clan Haldane's apparatus was used for analysing CO_2 and in the gas samples and the CO_2 and O_2 tensions calcula in the usual way.

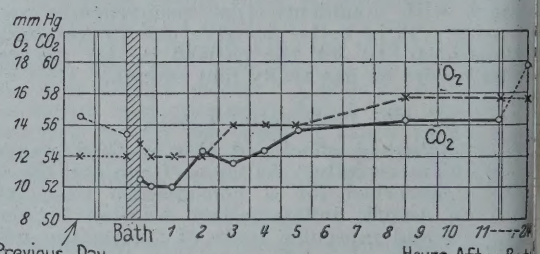
FIG. 2.



CO_2 and O_2 tension in gas under the s (rabbit) for 110 hours, following the s cutaneous injection of atmospheric

After the injection of 750–1000 c.cm. of air in the subcutaneous tissue of unnarcotised rabbits was necessary to wait until CO_2 and O_2 tensi became constant before beginning any experime I can fully confirm Campbell's statement that C equilibrium is established in about 1 hour, O_2 equ brium, however, not before 1½–3 days after i

FIG. 3.



Standing effervescent Nauheim Sprudel bath of 82·4° F., 30 minutes' duration. CO_2 and O_2 tension in gas under ski

injection. The final CO_2 and O_2 tensions provi to be in complete agreement with those found Campbell, the CO_2 tension being 45·52 mm. Hg, t O_2 tension 20–26 mm. Hg in the majority of t experiments. The equilibrium once established, t long-continued constancy of the tensions in a p ticular animal is remarkable (Fig. 2).

In order to obtain reliable results as to the effe of the Nauheim baths, care had to be taken that t animals did not inhale CO_2 which might escape fro the bath, as inhalation of CO_2 produces hyp ventilation, which leads to increased output of C and thereby influences the subcutaneous gas tensio I therefore analysed the CO_2 content of the 5 cm. above the surface of Nauheim standing eff vescent and running effervescent baths, and confirm the view that, in spite of the very large quantity

O_2 in the water, only very little escaped into the air, ıe CO_2 percentage being not more than 0·3 per ent.—this property being a characteristic of natural O_2 baths. Above strongly running effervescent ıths only, CO_2 was expelled mechanically, so that ıe air above the bath contained a relatively higher ercentage of CO_2. Therefore, a ventilator was then ıed in all experiments, thus ensuring that the CO_2 ontent of the inhaled air did not exceed 0·1 per cent. ı any experiment. The course of the experiment as the following: A rabbit was given an injection f 750–1000 c.cm. atmospheric air into the sub-ıtaneous tissue spaces by the method described ove. Four to five days later I satisfied myself that ıe CO_2 and O_2 tensions had become constant. his constancy was assured if the analyses of two mples of the gas under the skin taken at an interval several (4–24) hours demonstrated the same values the gas tensions. Then the animal was put into e bath, a further series of gas samples withdrawn om the gas under the skin at different intervals ter the bath, so that a full record of the influence the bath on the gas tensions was obtained.

The results of my investigations—10 experiments th 68 determinations of gas tensions—in which I used standing effervescent and running effervescent baths of the Nauheim spring VII, of 80–86° F. and 8–45 minutes' duration, are that a considerable fall of CO_2 tension in the gas under the skin was observed in all experiments. The decrease was 4–6 mm. Hg in the majority of the experiments, and ranged tween 1 and 10 mm. Hg, the average being mm. Hg. The minimum of CO_2 tension was ually observed ½–1 hour after the bath ended, e previous level being reached some hours later. ı the following day the CO_2 tension very often ved to be above the previous level. The O_2 tension s increased in 50 per cent. of the experiments to mm. Hg on an average, in the remaining 50 per nt. it was unaffected by the bath. The O_2 tension s observed to reach its maximum later than the nimum of the CO_2 tension. On the following day e O_2 tension either remained raised or fell to a lower el than before the bath (Figs. 3 and 4).

Plain water baths of the same temperature and ration proved to have the same effect on the CO_2 sion; they always caused, however, a fall also the O_2 tension averaging 3 mm. Hg, whereas the uheim baths, as shown above, increased the O_2 sion or did not alter it (Fig. 5).

In order to interpret these results we have to sider, on the one hand, pharmacological research ried out by the same method; on the other hand, earch on the Nauheim and other natural CO_2 rmo-saline baths by other methods. Realising t the subcutaneous CO_2 tension is about the same the alveolar CO_2 tension and that both are luenced in the same way and to about the same ent by experimental interferences (Campbell, mpbell and Hill), it is easily understood that reased ventilation is an important factor in ounting for the diminution of the subcutaneous O_2 tension as observed as a consequence of the Nauheim baths. This is analogous to the diminution of alveolar CO_2 tension by a great number of stimuli causing hyperventilation—e.g., baths, massage, &c. It has been proved repeatedly that baths lower alveolar CO_2 tension and, moreover, that cool, natural CO_2 baths lead to increased ventilation (Liljestrand and Magnus).

However, this interpretation is not sufficient to explain the increase or stability of the subcutaneous O_2 tension, Campbell having shown that hyperventilation produces a fall of both subcutaneous CO_2 and O_2 tensions. To understand these changes of O_2 tension the change of peripheral circulation has to be taken into consideration. We know that cardiac stimulants in corresponding doses produce changes in subcutaneous CO_2 and O_2 tensions in the same direction and to about the same extent as those observed in my experiments. A comparison between the influence on subcutaneous CO_2 and O_2 tensions of caffeine on the one hand, proved by Campbell, and a natural Nauheim effervescent bath on the other, illustrates the similarity in action of the two interferences.

As, moreover, vasoconstricting drugs (e.g., adrenalin and infundin) and temporary stopping of the circulation by histamine cause the reverse (i.e., an increase in CO_2 and a decrease in O_2 tension) (Campbell), we have every reason to interpret the results of this experimental study by assuming that the influence of the Nauheim baths on the peripheral circulation consists in the increase of the

peripheral blood flow—the peripheral blood-vessels, capillaries, as well as the larger blood-vessels, being dilated.

This interpretation and conception is in perfect agreement with the results of other research work on the influence of natural Nauheim baths on circulation. Theodor Schott earlier made the same assumption on the ground of clinical observations and of blood-pressure determinations which showed a lowering of blood pressure in hypertension by Nauheim effervescent baths, even if below the point of indifference. This view is supported by the work of Strasburger and his co-workers, who showed an increase of the volume of the arm by plethysmographic examination and, by means of the mirror sphygmograph, a decrease of the velocity of the pulse-wave as effects of Nauheim effervescent baths on peripheral circulation. Hediger's new research work on the influence of natural CO_2 baths on pulse volume, carried out by his own method, leads to the same conclusion. He thereby confirmed the results, obtained by capillaroscopic investigation, which showed dilatation of the capillaries in cool CO_2 baths, and extended them to the assumption that also the deeper lying blood-vessels are dilated. This effect on the peripheral circulation was not shown by the plain water baths, which never increased the subcutaneous O_2 tension. The different effect on the subcutaneous O_2 tension produced by mineral water baths compared with plain water baths of the same temperature proves that in the action of mineral baths the temperature is not the only decisive factor, but that there is a specific effect of the CO_2 and also perhaps of the salts. Moreover, Campbell showed that changes in air temperature between 0° and 37° C. did not cause any appreciable change of the tension in the gas under the skin. When changes such as have been observed as a consequence of Nauheim baths were obtained by over-heating the animal with a carbon-arc lamp, the rectal temperature rose by 3° F., whereas cool natural mineral baths decrease the rectal temperature (Liljestrand and Magnus).

Still another point of more theoretical interest is elucidated by these researches. We have to realise that the CO_2 level of the subcutaneous tissues is lowered considerably by the baths used, and we have had to explain this fact by an increase in CO_2 output by increased ventilation. The results with regard to the subcutaneous CO_2 tension, therefore, clearly disprove the often-quoted opinion of Winternitz that the increase of CO_2 output in CO_2 baths, and the increase of the respiratory quotient to the value of more than unity, form an analytical proof of the resorption of CO_2 through the skin from the CO_2 bath. The results of my experiments, however, are in perfect agreement with the results of Liljestrand and Magnus's investigations in man, by which these authors showed that the rise of the respiratory quotient to the value of more than unity as a consequence of the CO_2 baths, is simply due to the washing out of the CO_2 of the body, thanks to the increase in ventilation caused by the bath. My investigations confirm the view that it is not possible to prove the resorption of CO_2 analytically, although clinical experience, as well as the vascular reaction characteristic of CO_2 baths, lead us to assume a local chemical action of resorbed CO_2 (Goldscheider). This opinion is compatible with the well-known fact that the skin plays a certain rôle in the excretion of CO_2. That the results of experiments on animals are applicable to human physiology only with a certain reserve need hardly be emphasised.

However this more theoretical point may be, these experiments are a new link in the chain of proofs that the Nauheim baths afford the possibility of giving a tonic treatment to heart patients by causing an alteration in peripheral circulation and by giving a tonic impulse to the heart. These investigations offer, therefore, a better understanding for the indications of the Nauheim treatment which have, of course, long been well known empirically, the chief indications being all those cases in which a tonic treatment of the circulation is needed; and also cases with genuine high blood pressure, for the reasons which foll from the points dealt with above. It would be beyo the scope of this paper to enter into the details these indications.

Clinical and Laboratory Notes

AN ATTEMPT TO CONTROL AN EPIDEMIC OF MEASLES.

BY D. MCCLEAN, M.B., B.S. LOND.,
LATE ASSISTANT PATHOLOGIST, HOSPITAL FOR SICK CHILDREN, GREAT ORMOND-STREET.

THESE observations made during an epidemic measles in one of the wards of the Hospital for Si Children may be of interest in view of the absence conclusive evidence of the ætiological relationship the Tunnicliff "green" coccus to measles.

History of the Epidemic.

Nov. 15th, 1927: One patient, admitted on Nov. 11 developed measles and was sent home. Another patie had developed what was thought to be rubella on Nov. 1(and died on Nov. 12th of pneumonia. On Nov. 22nd patient who had been in the ward since Oct. 28th develop measles. On Nov. 23rd all the patients (26) were test intradermally with a 1/250 dilution of a filtrate from 48-hour growth of a subculture from the Tunnicliff "green coccus. This subculture had been supplied by Dr. R. O'Brien. I had no evidence that the filtrate contained a toxin. These skin tests were read after 6, 10, and 24 hou and were all negative. Six hours after these tests n patients, with no previous history of measles, were giv 10 c.cm. of (?) antitoxic serum intramuscularly. This ser was supplied by Dr. O'Brien, who stated that he had evidence that it contained any antitoxin. A note, kind supplied by him, on the preparation of this serum will quoted later. Four patients with no previous history measles went home before any serum was available. Thr of these developed measles at home.

Of the nine patients who received this serum two develop measles six days after injection of serum; one develop measles three weeks after injection of serum; four did n develop measles in hospital and had not developed a catarrhal or other symptoms 16 days after discharg one child could not be traced (no reply was received fr the parents); one child was readmitted on Dec. 1 (20 days after receiving serum and 11 days after dischar with broncho-pneumonia and laryngeal stridor, and died the same day. There were no signs or history of measl Post-mortem examination showed broncho-pneumonia on

In addition a small supply of convalescents' meas serum was available from two patients only; it was "pooled." This was given to three selected cases who w gravely ill and to whom an attack of measles would h been very dangerous.

1. Nov. 20th: 5 c.cm. of this serum were given to a c of convalescent pneumococcal septicæmia. This patient v discharged on Dec. 2nd, and had not developed measles Dec. 20th.

2. A boy with marasmus, who developed catarrhal symptoms with Koplik's spots on Nov. 29th was given 5 c.cm. of convalescent serum. He died on Dec. 2nd. No rash had developed, and therefore the blanching power of the Tunnicliff goat antitoxin could not be observed.

3. A case of paratyphoid was given 5 c.cm. of human convalescent serum on Nov. 29th. She developed measles on Dec. 13th (14 days later).

Dr. O'Brien supplied a small quantity of antitoxin prepared from a goat by Dr. Ruth Tunnicliff of Chicago Intradermal tests with 0·1 c.cm. of this were carried out on four children during the catarrhal period preceding the development of the rash in order to observe the Debré blanching phenomenon. One patient died before any rash developed and three showed no blanching.

The superintendents of the fever hospitals, to which the three "protected" cases who developed measles were sent, did not consider that there was any definite modification of the course of the infection. All three were moderate, uncomplicated measles.

Summary.

When considering these results it should be remembered that there was no evidence of the toxicity of the filtrate used in skin testing. The "antitoxin" supplied by Dr. O'Brien was prepared from horses instead of goats, and he stated that he had no evidence that it contained any antitoxin.

(1) Twenty-six patients in one ward, aged from 1 month to 12 years, among whom cases of measles had occurred, were tested intradermally with filtrate from the Tunnicliff "green" coccus. Nine of these patients gave no previous history of measles. No positive skin reactions were obtained.

(2) Nine children with no history of measles were given "antitoxic" serum. Of these, three developed apparently unmodified measles six days and a fortnight later.

(3) Of four presumably susceptible children who were not given any serum, three developed measles at once.

(4) Three children were given convalescent serum. One child did not develop measles. One infant who was probably developing measles at the time of injection died three days later with no rash. The third child developed apparently unmodified measles a fortnight later.

(5) The Debré blanching reaction with Dr. Tunnicliff's antitoxin could not be obtained in three patients.

Dr. O'Brien has supplied the following note on the "green" coccus:—

"Dr. Ruth Tunnicliff very kindly sent me cultures of the 'green' coccus which she had found constantly present in the throats of patients suffering from measles and which she was inclined to think, from immunological evidence, was the cause of measles.

"Dr. C. C. Okell, working in London, found the organism present in all the swabs from several dozen cases of measles kindly supplied by Dr. F. M. Turner and other clinical friends. We therefore injected three horses for several months with increasing doses of culture filtrate, following in all details the technique successfully used for making scarlet fever antitoxin unconcentrated and concentrated. We had no means whatever of deciding whether the serum contained any antibody. It seemed that the only proof might come from giving the serum to half of groups of people recently exposed to infection and not having suffered previously from measles. Supplies of the serum were sent to 15 medical men who wished to try it. Inquiries have brought a certain small amount of information, which I am afraid is quite unconvincing. Some of the serum was used for treatment, and in some patients was considered by the clinician in charge to have had a definitely favourable effect. Most was used in attempts to prevent infection. Unfortunately, in most of the observations the serum was given to all contacts and not to half of those with no previous history of measles. It would take considerable space to give all the figures, but they do not to my mind convey any clear proof of protection. The few attempts that have been made to get a Debré blanching phenomenon and also a skin reaction have been unsatisfactory.

"I am greatly indebted to Miss Tunnicliff for keeping me in touch with her work. In a recent letter to me she has reviewed, with restraint, the evidence in favour of her organism and has suggested the use of living cultures for immunisation; unfortunately at the moment we cannot arrange for this.

"I must freely admit that the amount of evidence against the claim of the Tunnicliff coccus to be the cause of measles is very meagre: it is difficult to get satisfactory clinical observations carried out, but I feel bound to take this opportunity afforded by Dr. McClean of saying that, to my disappointment, our work has not supplied any clear evidence in favour of the 'green' coccus."

Conclusions.

These results do not suggest that the filtrate contained any toxin nor the serum any antitoxin. There was no evidence of any antitoxin in the goat serum when tested in three patients. The evidence of protection afforded by the serum of convalescents was not satisfactory in view of the small number of patients and the fact that the serum was not pooled.

These results, which are admittedly inconclusive, are presented in the hope that they will provoke the publication of the observations of other workers in the same field. It is important that the ætiological relationship of the Tunnicliff coccus to measles should be established or disproved as soon as possible. The evidence for the prophylactic and therapeutic value of serum from convalescents should be recorded in order that those public authorities through whose hands many measles cases pass may be induced to organise the supply of suitable serum for the use of practitioners and institutions.

My thanks are due to Dr. Robert Hutchison for permission to make these observations on patients under his care; to Dr. O'Brien of the Wellcome Research Laboratories for information and the supply of the materials used; to Dr. David Nabarro, the Director of the Department in which the work was done, and to Dr. C. F. Harris, the house physician, for help in reading the tests, administering the serum, and the collection of results.

A CASE OF SARCOSPORIDIOSIS.

By A. Srinivasulu Naidu, L.M.S., B.S.Sc. Madras,
assistant to the professor of pathology, medical college, madras.

The interest of this case lies in the rarity of human sarcosporidiosis and the identification of the species discovered. According to E. R. Stitt (1923) only three authentic cases have been reported. In one case they were found in the biceps, in another in the laryngeal muscles. According to H. B. Fantham (1916) six cases are on record.

A Hindu male of 55, without occupation, was admitted to the third surgeon's wards in the General Hospital, Madras, giving 15 days' history of an abscess of the left chest wall, which had started as a small pustule and gradually enlarged to about 2 inches in diameter. No previous illness. Wassermann reaction negative and urine normal. He was fairly well nourished and had no pyorrhœa. The edges of the ulcer were indurated, the base was fungating and adherent to the muscles, and presented sieve-like openings all over. The ulcer was provisionally diagnosed as "carbuncle chest" and excised under gas. The temperature remained normal all through the 29 days he was in hospital. The excised tissue was examined and reported on as sarcosporidiosis.

Macroscopic appearances.—Just over the nipple there is an irregular excavated ulcerous area roughly 1½ by 1 in., with undermined edges and irregularly globular projections from the sides and the base of the ulcer. The margins are thick, rounded, slightly inverted, dense, and sclerotic. On section the ulcer extends only to a portion of the subcutaneous fatty layer; the underlying areolar tissue is thickened and laminated. The pectoral muscles show pin-point white specks and fine lines.

Microscopic appearances.—Numerous sarcocyst tubes are seen invading the muscle-fibres. The cysts containing the sporozoites are not uniform in size or shape. Some are large and mature with well-developed septa, while others are immature. From the tissue received the entire length of the tube could not be discovered and dissected out. The average breadth of the mature cysts is 195 to 240 microns, and there are, on the average, 64 septa, which unite in the central area as a well-defined honeycomb-like structure. Between the septa the sporozoites are packed full, whereas in the central honeycomb-like area only a few can be seen. The younger ones appear nearly round, the mature ones oval or sausage-shaped. There is a definite hyaline, non-granular, non-laminated, non-striated cyst wall of 3·5 microns

thickness all round. This stains slightly pink with eosin. The muscle-fibrils are splayed out and overlap the cyst at the ends. Two cyst cavities present peculiar appearances. In one there is a ring of large, eosinophile, non-granular, mononuclear cells with abundant protoplasm all round, both on the inner and the outer side of the cyst wall; a few of these mononuclears are seen within the cyst cavity, amidst a certain quantity of granular débris and destroyed cyst septa. There are a few polymorphonuclears to be seen outside and inside, some in the actual process of migration into the cyst cavity. The other cyst cavity is packed full of the eosinophile non-granular mononuclears and a few polymorphonuclears. No sporozoites are visible, either inside or outside the cyst.

The average dimensions of the spores are: length, 9·7 to 12·7 microns; breadth, 2·9 to 4·4 microns. Each sporozoite is sickle-shaped, with one extremity sharp and thin, and the other somewhat rounded. The nucleus, which is oval with its long axis parallel to the length of the spore, is at a distance of one-fourth of the length of the sporozoite from the thin end. At the broader end a deeply chromatin-staining spot (Leishman stain) is visible. In every spore one or two (usually two) ruby-red, small chromatin granules are visible between the deep-stained spot at the broad end and the nucleus. The rest of the protoplasm stains a ver light pink. The size of the nucleus is 3·6 by 2·0 micron No spore wall can be made out. Some spores are plum some lean, and others short, but the majority are of the sam shape and size. The plump ones assume an elongated-lan shape.

I sent the preparations to the University Edinburgh, and in June of last year they we examined by Prof. J. H. Ashworth, F.R.S., wh stated that the parasite is septate and this, alon with the general structure of the spore, indicat that it belongs to the genus sarcocystis. Many the spores, he said, are almost straight. In son respects they resemble those of globidium. "Th nucleus is near the broad end but in addition the is nearer the middle of the spore a deeply stainin granule, and in some cases more than one."

I have to thank Capt. P. N. Basu, professor pathology, Medical College, Madras, and Dr. G. James, the third surgeon, General Hospital, Madra for permission to publish these notes.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF NEUROLOGY.

A MEETING of this Section was held on March 8th, with Dr. EDWIN BRAMWELL, the President, in the chair, when Dr. KINNIER WILSON opened a discussion on

NARCOLEPSY.

He said that the word had not occurred in the indices of *Brain* between 1899 and 1926, although the older literature contained numerous references to narcolepsy. The recent reawakening of interest might be one of the periodic waves so common in neurology, or might be due to a greater frequency of the condition during the past few years. He had been on the look-out for it for 20 years, but had never seen an adequate case of it till 1927, when he had seen four cases one after the other. Others had noticed the same sequence of events. Many of these cases, however, dated back for years, and could not be the result of the recent epidemic of encephalitis. In no circumstances could narcolepsy be regarded as a disease; it was a symptom or syndrome. Consideration of the disorders in which there was increase of sleep might throw light on those of absence of sleep. It was regrettable that people were rushing into print over the narcolepsies and often ignoring previous writings on the subject.

The first patient had had irresistible attacks of sleep for two and a half years, sometimes sleeping many times a day. In addition, he had had attacks, like those described by Gélineau and known as cataplexy, in which he sank to the ground or felt that he was going to do so. He had no organic nervous disorder and, like most of these cases, had attended hospital without improvement until tired of doing so.

The second case was that of a young man who had had cataplexy for 19 months, the first attack seizing him when he learned that he had won £5 in a football sweep. Since then he had had repeated attacks under the influence of —in many instances—quite trivial emotion. He had also developed typical sleep attacks, and if he tried to avert the onset of sleep a cataplectic attack would develop. Examined in one of these cataplexies, he had been found to be in a condition of massive atonia, with absent knee-jerks, an almost imperceptible flicker for a corneal reflex, and an extensor plantar response. In about two minutes he had said "I'm all right, sir," and had got up. When again tested, his plantar response had become flexor and his knee-jerks had returned.

The third patient was a man who had had symptoms since the end of the Boer war. In addition to sleep and cataplectic attacks he had had attacks of catalepsy or trance. When sitting quietly in a chair something would steal over him and he would suddenly find himself unable to move a single joint through the fraction of a millimetre. He would lie with closed eyes, to all appearances normal, and yet "someone could come in and murder him and could not move." He had burned his fingers with t cigarette held between them.

The second case had also begun to develop cataplect attacks of the nature of trance or catalepsy, and the had actually come on in his dreams. He had dream that he could not move or make a sound, and had th awakened, but continued to lie to all intents a purposes asleep; though aware of all that was goi on, he was unable to move a finger.

Two Varieties of Narcolepsy.

If narcolepsy were regarded as a symptom, excitat in more than one direction, light would be throv on phenomena lying on the borderline between t physiological and the psychical. It was useful distinguish cases in which there were attacks cataplexy and of short sleep from those in wh ch the was prolonged sleep. Dr. Wilson has collect 45 cases of the first type from the literature of t last 40 years. The second group led into the regi of the symptomatic narcolepsies—i.e., those associat with organic disease, particularly with tumo around the third ventricle. Righetti had collect 775 cases of cerebral tumour, of which 115 had sho pathological sleep; 34·7 per cent. of tumours of t thalamus and third ventricle, 27·9 per cent. arou the medulla and pons, 26·5 per cent. of those in t vicinity of the hypophysis, and 25·6 per cent. ab the corpora quadrigemina and pineal showed t symptom, whereas only 10 per cent. of cases tumour of the central gyri had any unusual sleepine Half a dozen different ætiological factors mi produce pathological sleep: epidemic encephalitis a trypanosomiasis were notorious instances. Dr. Wils was most unwilling to separate all these as if th depended on different underlying mechanisms. preferred to say that they all had some as yet unkno basis.

In many instances the patients had not, in fa been "asleep" during attacks, as they had been aw of what had been going on around them, althou unable to move and looking as if asleep. Moreov there were all gradations between sleep and cataple Emotion might precipitate either.

A larval case was that of a young man who found t if he looked at any object he became unable to turn his e away from it, and if he gazed fixedly at anything in a reve he sank into a state of immobility. He had also an alter tive form of cataplexy, feeling that he must fall to the grou although he had never actually done so, under conditi of very slight psychological stress.

Cataplexy, Narcolepsy, and Epilepsy.

The sufferer from myoplegia or periodic fam paralysis took hours to develop the flaccid pa and loss of reflexes, while the cataplectic took secon but the condition was the same when developed. T resemblances between narcolepsy and epilepsy w greater than the differences, and the two might b

pair of Jackson's "corresponding opposites." The patient in an epileptic attack was unconscious and his limbs were in motion; in a cataplectic attack he was awake and immobile, the consciousness of the cortex fully active, with absolute outfall of tone and motility at low level. Resemblances included the recurrence, the short attack, the sudden onset, and the interference with consciousness. Epilepsy and narcolepsy had been recorded in the same patient in a number of cases.

A patient of Dr. Wilson's, a man of 21, had had nine or more epileptic fits between the ages of 2 and 14, at which age they had ceased. Recently, however, he had found that uproarious laughter would bring on cataplectic attacks in which he lost himself, turned white, fell, or sat still unable to move.

It was very undesirable to differentiate epilepsy and narcolepsy as if they were fundamentally distinct, and a prima facie case could be made out for their resemblance. They might have analogous physiological mechanisms. If many of the sleep cases were really trance-like states, cataplexy, immobility with awareness, then the phenomena were phenomena of inhibition, and the sensory stimuli in these cases were inhibitory instead of excitatory. Quite a large part of the phenomena of ordinary epilepsy was inhibitory. The patient with petit mal became immobile, dropped what was in his hand, stared. In the aura he might become blind or deaf. In the narcolepsies the same condition was carried further, and practically all the phenomena were phenomena of inhibition. Pavlov had shown that sleep was pure cortical inhibition descending to the mid-brain. If it did not so descend, the animal was not asleep, but in a state of catalepsy, fixed, and staring, with flexibilitas cerea. The catalepsy resembled what was seen in many cases of narcolepsy. Occasionally, Jacksonian epilepsy, after a sensory aura, might take the form of loss of power instead of twitching. Complete atonia was seen after the "knock-out" on the point. It would be interesting to know if the knocked-out pugilist lost his knee-jerks.

Discussion.

Dr. C. C. WORSTER-DROUGHT said that he had four cases of narcolepsy under observation and could confirm Dr. Wilson's observations. He had been looking out for cases for years, but had only seen them within the last 18 months. In his patients the sleep attacks had preceded the cataplectic attacks by two years or so. He had induced a cataplexy in one case by telling a funny story and had noted the extreme atonia and absence of arm- and knee-jerks. He regarded narcolepsy as a form of some symptom-complex indicative of an underlying cerebral disturbance. A case of syringomyelia had fallen asleep without provocation; he had had no definite cataplexies, but stated that when he laughed heartily he felt as if he were doubling up. There was a very narrow borderline between cataplexy and narcolepsy.

Sir JAMES PURVES-STEWART pointed out that in normal sleep one of the most important and constant phenomena was atonia, which was quite sufficient to account for the loss of knee-jerks. If the third ventricle were inflated with air from above, the patient at once fell into happy, peaceful sleep. If it were inflated from below, filling the subarachnoid space at the same time, there might be considerable meningeal reaction with headache. The paroxysmal character of narcolepsy had not yet been explained, and no static lesion could explain it. That was a crucial point.

Dr. WILFRED HARRIS said that it was not the sudden blow to the sensorium which produced the "knock-out"; it was the sudden violent jerking back of the head on the neck. From the technical point of view nothing was stationary, perhaps; but static lesions, in the ordinary sense of the word, could produce paroxysmal phenomena—for instance, trigeminal neuralgia.

Dr. GRAINGER STEWART had seen two or three cases of narcolepsy in the last two years, and described a case in a child with epilepsy. The child's eyes drooped, and she sank down on the table on lifting the spoon or fork with the first mouthful of a meal. He had come to the conclusion that the attacks, originally taken for petit mal, were really cataplectic.

Dr. P. C. P. CLOAKE read a letter from a patient describing vividly her narcoleptic attacks. She was in a state of mental confusion after the attacks, which appeared to be a mixture of sleep and cataplexy. As a normal individual dropped to sleep, associations became freer and freer and less connected by logical bonds. It was impossible to think of a wave of inhibition passing over the cortex, except in the sense that there was a sudden cessation of evolution of neural or psychic energy. Extensor plantar reflexes had been obtained during sleep.

Dr. H. COHEN had seen eight cases of so-called narcolepsy in recent years, three of them sequelæ of epidemic encephalitis. One patient's attacks had been precipitated by a sudden start of any kind, particularly a noise. There was an epileptic family history. Another patient, who had a spastic paraplegia dating from infancy, fell into a cataplexy on any loud noise and for 30 or 40 seconds was conscious but unable to speak, showing typical mild clonic movements. In a third case noise produced typical epilepsy. He had seen the same gradation, though not so extreme, with uproarious laughter. These cases showed some definite relationship between epilepsy and so-called narcolepsy.

Dr. GORDON HOLMES related several cases of narcolepsy. One was that of a boy who had been subject to epistaxis, which ceased when the narcolepsy began. The second suffered from cataplectic attacks brought on by annoyance. A third patient, a clergyman and schoolmaster, had suffered from headaches and attacks of falling and of irresistible sleep. He had small scotomata in each upper right and left quadrants, indicating an organic lesion. Curiously enough, his attacks had become less frequent after a course of thyroid, and had now disappeared. Dr. Holmes disputed Dr. Wilson's statement that the word sleep should not be applied to people who were conscious to some degree of what was happening around them. This was a stage of normal sleep.

Dr. R. D. GILLESPIE described a patient who had cataplectic attacks provoked by slight emotion, but not by serious frights. Another case had done well on hyoscine hydrobromide. He had observed a man in an attack two years ago and had found knee-jerks and plantar response absent and a slight ptosis of one eyelid with immobility of the pupil. Another patient was subject to attacks after a hot bath, but found that splashing cold water in his face enabled him to avoid them.

ROYAL INSTITUTE OF PUBLIC HEALTH.

PROBLEMS IN MEDICO-LEGAL PRACTICE.

ON March 7th Mr. Justice HUMPHREYS took the chair at a meeting of this Institute, when Dr. ROCHE LYNCH began a lecture on this subject by discussing

Criminal Abortion.

This was, he said, practised to a greater extent to-day than ever before, and thus presented one of the most pressing problems of forensic medicine. Quoting the relevant statute, he pointed out that it was the intention which constituted the crime; it was not necessary for an abortion to take place and, except where a woman procured her own miscarriage, it was equally a crime whether she were pregnant or not. Moreover, the statute did not in fact make any exception for abortion procured by doctors for medical reasons. Certain doctors seemed recently to have altered their opinions and to practise the operation in cases which, according to the older views, amounted almost if not quite to an illegal operation. When a doctor was called in to a case of attempted abortion he was faced with a very difficult problem of conduct. The Royal College of Physicians of London had

examined the question very carefully in 1916 and had published rules which stated :—

1. That a moral obligation rests upon every medical practitioner to respect the confidence of his patient and that without her consent he is not justified in disclosing information obtained in the course of his professional attendance on her.

2. That every medical practitioner who is convinced that criminal abortion has been practised on his patient should urge her, especially when she is likely to die, to make a statement which may be taken as evidence against a person who has performed the operation, provided always that her chances of recovery are not thereby prejudiced.

3. That in the event of her refusal to make such a statement he is under no legal obligation to take further action, but he should continue to attend the patient to the best of his ability.

4. That before taking any action which may lead to legal proceedings a medical practitioner will be wise to obtain the best medical and legal advice available, both to ensure that the patient's statement may have value as legal evidence, and to safeguard his own interests, since in the present state of the law there is no certainty that he will be protected against subsequent litigation.

5. That if the patient should die he should refuse to give a certificate of the cause of death and should communicate with the coroner.

The College had been advised : (*a*) that a medical practitioner was under no legal obligation either to urge the patient to make a statement or, if she refused to do so, to take any further action ; (*b*) that when a patient who was dangerously ill consented to give evidence her statement might be taken as a dying declaration or statutory deposition.

Dr. Lynch then referred to Sir William Willcox's letter in THE LANCET of Jan. 9th, 1915, expressing the opinion that where there was conclusive objective evidence of criminal interference the duty undoubtedly rested with the medical practitioner to inform the legal authorities ; his duty to the public in such a case overrode any obligation of professional secrecy. A learned judge had stated that no jury would convict a doctor if proceedings were subsequently taken against him for betraying confidence. On the other hand, the doctor would be put to great expense and inconvenience in obtaining that verdict. When abortion was properly performed the mortality was almost nil, but the methods used by the criminal abortionist were never those used by medical men, and an important reason for the rigorous prosecution of the abortionist was his danger to society.

Drugs Used as Abortifacients.

The varieties and combinations of harmless drugs sold for this purpose were legion. The vendor traded on the ignorance of unfortunate women, and in the lecturer's submission the sale of these substances was fraudulent. A girl had spent her life savings—about £40—on a treatment supplied to " dissolve the contents of the womb." The pills consisted of caffeine, iron salts, starch, garlic, and some herbs, of which the main ingredients were cloves and sage. The capsules contained urotropin, and the suppositories cocoa butter and zinc oxide. Not only was the treatment quite innocuous, but its cost was only a few pence.

Harmful drugs included aloes, quinine, ergot, pituitrin, strong purgatives, and some essential oils. Some caused painful contractions of the large intestine which spread sympathetically to the uterine musculature ; others caused pelvic congestion or irritation of the urinary tract. Ergot and quinine alone had any direct action on the uterus. The drugs were usually supplied in small doses, which made it very difficult for the medical witness to give positive evidence on whether they were harmful or not. Many of them could be bought without question, and it was no business of the chemist's to ask what they were wanted for. Even if drugs to cure amenorrhœa were asked for the chemist often forgot his duty to refer the customer to a doctor. Herbalists and less reputable establishments sold these drugs in large quantities at enhanced prices. The only regrettable feature about the recent case of Rex *v.* Bacon and Bolton was that it had been impossible to bring into the charge newspapers which had published advertisements of the business. If advertisements of this kind could b stopped, much of the trade would be suppressed Poisonous substances had from time to time bee used for abortion, including arsenic, mercury, pho phorus, and lead. In this case the abortion wa rather a complication of the acute serious illnes caused by the poison than a result of the drug taker The popularity of diachylon plaster as an abortifacien had greatly diminished since it had been placed i Part I. of the schedule. In the majority of case abortion would not occur even after large doses o the drugs sold, yet undoubtedly they did succee in certain cases. The successful cases did not attai publicity, but it was not credible that the preparation were entirely useless, seeing the great amounts of ther which were sold.

What is a " Noxious " Drug ?

From a medical point of view a noxious thing wa one which would cause illness, permanent injury, o death. There had been so many legal pronouncement on the meaning of the word that the result wa confusing. Two opinions threw light on it.

Archbold said : " It is not sufficient that the defendan merely imagined that the thing administered would have th effect intended, but it must also appear that the substanc administered was either a poison or a noxious thing.

2. " Where a substance is not a ' poison,' then, althoug if when administered in small quantities it may be innocuou and useful, yet if the quantity administered by the defendan is noxious, the quantity of the substance so administered b him is a ' noxious thing ' within the statute. On the oth hand, if the substance when administered in large quantiti is noxious yet if, in the quantity administered by th defendant, it is innocuous, he is not guilty of the admini tration of a ' noxious thing ' within the statute.

3. " Whether it were, in fact, a substance likely o calculated to produce that effect seems to be immateria provided the intent be proved, and the substance were poison or other noxious thing."

Mr. Justice Darling had held that where the incite knew that the drug was not, in fact, noxious o capable of procuring abortion, but knew that th woman would take it in the belief that it would hav that effect, the inciter was not guilty of an offenc but the woman was guilty of attempting to comm abortion. He had further held that if the stuff wer harmless the accused could be properly indicted fo obtaining money by false pretences, and that, further advertisements of the preparation appeare the newspaper authorities would find themselves i the dock. Nevertheless, when all was said, the questio of " noxiousness " was for the jury to decide, and the decision would rest largely on the evidence given b the expert medical witness.

The Select Committee on patent medicines ha reported in 1914 that " the existing law is chaotic an has proved inoperative, and successful prosecution fo fraud in the advertisement and sale of secret remedi is fraught with the greatest difficulty."

Mechanical Abortion.

Any foreign solution injected into the uterus woul cause it to expel its contents ; soapy water was mos commonly used. Frequent syringing of the vagin with hot liquids might produce abortion, probabl through solution of the mucous plug in the cervica canal. The varieties of sharp rigid instruments use for the purpose were legion. An occasional complica tion to their use was death from shock, immediate o delayed. Probably fear of the unknown, secrecy an the knowledge that the act was illegal all played the part in producing it. The electrical method consiste in applying a pad soaked in salt solution to the cervi and another to the abdomen. When an electr current was passed between them the uterus ofte contracted. This type of crime was most difficu to detect, and probably impossible in the absence o a burn or mechanical damage. In many cases dru treatment was combined with mechanical treatmen The limitation of these practices must depend large on the medical profession. A prosecution seldom too place unless a medical man had been called in. Th doctor might look to the lawyer to make represent

ions for an amendment of the law so as to allow more tringent control.

Blood Groupings, Blood Stains, and Paternity.

Dr. Lynch then described how the four blood roupings might be used to test the claim of a prisoner hat the blood on his clothes came from a cut made hilst shaving and not from his alleged victim. The st would work definitely on a blood stain a year or o old. The examination of agglutinable property n the corpuscle and agglutinin in the serum provided double test, and would be as valuable to prove the nocence of the innocent as the guilt of the guilty. nother application of blood groups was in the etermination of paternity. They followed strict endelian laws, and two parents of Group IV. could ave only children of Group IV. If a mother belonged Group II. and her baby to Group IV. a man of roup III. could not possibly be the father.

The Distinction between Abortion and Birth Control.

Mr. Justice HUMPHREYS pointed out the grave crease in the practice of criminal abortion in this untry. It was most important to bear in mind at birth control and criminal abortion were two tally different things. The one was highly criminal; e other might be desirable or undesirable, but it as not criminal. It was the greatest possible mistake r those who wanted to impress on a woman the nger and wrongfulness of abortion to add that it as equally wrong to try to avoid having children. any women felt that having children or not was tirely a personal matter, and if they thought their edical or legal adviser wrong about one thing they re very apt to think him wrong about the other. r. Justice Humphreys doubted whether he had any mpathy for the woman who tried to procure a iminal abortion and failed to get the stuff she anted. He had never advised the prosecution for lse pretences of persons who were deceiving those o ought to be deceived. What must be put down s the sale of drugs that the purveyors knew would all probability be used to procure abortion. In e case of Rex *v.* Bacon and Bolton the defendants d not, he was happy to say, been successful in oiding criminal responsibility because the dose ey had recommended was more probable than not fail. He saw no difficulty about the meaning of e word "noxious." All that the medical witness d to remember was that the question of intention s perfectly immaterial. A thing did not become rmful because someone wished it to be harmful. as the drug one that was likely to procure abortion? s the only question he had to consider. If he replied at in many women that drug in that dose would ocure abortion but in a great many other women would not, then he might leave it to the judge to ect the jury as to whether the drug was noxious not. One judge, at least, in such a case, would say at there was ample evidence upon which they uld find that it was so noxious.

MEDICAL SOCIETY OF LONDON.

A MEETING of this Society was held on March 12th, . H. W. CARSON, the President, in the chair. A per on the

CARRIER PROBLEM

s read by Dr. J. E. MCCARTNEY, who said that man carriers of infection were important from the int of view of the bacteriologist, the sanitarian, epidemiologist, and the physician. Their nomic aspect also was of considerable importance, ough it did not seem to be often considered. In arge Metropolitan Asylums Board institution there re always some 40 or 50 diphtheria carriers, h of which cost about £4 per week. Among eases which human carriers transmitted were hoid fever, dysentery, diphtheria, meningococcal ections, scarlet fever, pneumonia, cholera, undulant er, poliomyelitis, sexual diseases, measles, mumps, chicken-pox, and perhaps influenza. Tropical disease he did not propose to deal with. A carrier, said Dr. McCartney, was an individual who harboured and transmitted pathogenic organisms without showing the usual evidence of infection. Signs of infection could be found in carriers if they were sought for, but they were not the usual signs. The first type of carrier was the convalescent, chiefly found in diphtheria and typhoid fever. All who suffered from disease were carriers in the sense that they could transmit infection; but they were not true carriers, because they showed the usual evidence of it. A convalescing patient, however, though clinically well, might still harbour the organisms. If such a patient harboured the germs of disease for only a short time he was known as a temporary convalescent carrier, and was not very important. If he harboured them for a longer period—arbitrarily given as 12 weeks in the case of diphtheria—he was described as a chronic carrier. The other type was the "contact" carrier, who acquired the organisms from a sick person or from another carrier, and did not manifest the disease. Later, the resistance of such a person might break down, so that the disease became evident in him. If so he would come into the category of "incubationary" carriers. Many people had disease in a mild and unrecognised form, and sometimes there might be four links in the chain of infection, the fifth person alone being obviously ill, which made it difficult to trace the course of an epidemic.

Diphtheria.

At present, said Dr. McCartney, the carrier disease of greatest practical significance was diphtheria. In this, the chronic convalescent carrier was very important; chronic contact cases did occur, but they were not so common. To estimate the virulence of diphtheria organisms it was necessary to test them by intercutaneous inoculation into the guinea-pig. People who harboured non-virulent diphtheria bacilli could not, in Dr. McCartney's opinion, cause fresh cases of diphtheria—a statement which was based on a large number of observations. Non-virulent diphtheria did not tend to become virulent, and the recognition of these non-virulent cases had liberated from institutional seclusion hundreds of persons. But it was necessary to carry out the test very thoroughly. Text-books stated that cultures from the throat should be examined 12 to 18 hours after being taken, because at a later stage the bacilli were apt to be overgrown and the chances of getting a positive result were diminished. The truth was that in the case of carriers the organisms were not actually growing in the throat, and they only began to grow rapidly about seven hours after being put into a tube of broth, this interval before growth being called the "lag" period. For testing carriers the culture must be left for 48 hours, the number of positive results being 50 per cent. greater at this time than it was after 24 hours. When organisms from a chronic carrier got into the throat they might be eliminated by the defence mechanisms of the body before they had had time to excrete enough toxin to exert their pathogenic effect and overcome the natural resistance of the body. The intermittency of carriers must be borne in mind, for it was clear that a few negative results did not prove that a carrier was cured. Cases might be negative for weeks and then suddenly become positive. At the North-Eastern Fever Hospital six consecutive negatives were required, extending over a period of six weeks, before a patient with diphtheria was discharged. Whether or not a patient would become a carrier could not be decided from the clinical course of the disease, but the mild cases seemed the more likely to become carriers, especially between the ages of 1 and 5, or to a lesser extent, 5 and 10 years.

The organism in the chronic carrier did not exist on the actual living tissue of the host, but on the product of the inflammatory reaction caused by other organisms. The usual site of the organisms in throat carriers of diphtheria was the tonsils or adenoids, but the most persistent carrier and the one most

difficult to deal with was that in which the bacilli were in the nose, where they seemed to thrive on the products of chronic rhinitis associated with deflected septum and abnormal turbinates. In a series of 95 carriers, 72 had been found to have some nasal affection. Every case with virulent bacilli had to be dealt with according to its particular characters. In a throat case, removal of adenoids and tonsils would cure, but in a nasal case the proposition was very different. Homologous vaccines would clear up probably 30 per cent. of the nasal carriers, since eradication of the organisms causing the inflammation on which the diphtheria bacilli lived might lead to a cure. A mild alkaline douche was useful for clearing up a purulent discharge.

Typhoid and other Carriers.

It had been shown, Dr. McCartney continued, that about 4–5 per cent. of typhoid and paratyphoid patients were likely to become carriers, and some American writers put the proportion much higher. The chronic carriers conveyed the disease by means of their fæcal and urinary discharges and by chronic abscesses and chronic inflammation of bone. Fæcal carriers represented 93 per cent. of all the cases. The bacilli usually resided in the gall-bladder and many of the patients had gall-stones. In examining the typhoid carrier an attempt should be made to get the contents of the small intestine, and this was helped by giving a calomel purge. Women constituted the bulk of typhoid carriers; there were but few cases in children. Outbreaks of the disease in mental hospitals always left a serious carrier problem, owing to the dirty habits of the patients, and typhoid and dysentery were ever-present troubles in asylums. In the search for carriers the Widal reaction was of little use. Treatment of typhoid carriers was unsatisfactory. Removal of the gall-bladder might cure the condition, but was it justified? For urinary carriers, urinary antiseptics might be tried, but in all these carrier cases the best course was to secure the willing coöperation of the person concerned, especially as regards promiscuous urination and strict cleanliness. The public health regulations were most unsatisfactory, as they did not give full power to deal with carriers unless they were actually engaged in handling food.

Bacillary dysentery was not important from the present standpoint. Many people who had never been out of this country might be harbouring the *Amœba histolytica*. Very few convalescents from meningococcal infections became carriers, and contact carriers rarely developed the disease. The organisms were located in the upper respiratory tract, and probably did not live in the tissues, but on the products of inflammatory reaction. 300 cases of scarlet fever had been examined at the main laboratory of the M.A.B. on their discharge at the end of seven weeks, and half had been found to be carrying the hæmolytic streptococci which caused scarlet fever; but in the summer months, when there were comparatively few such cases in the wards, the proportion fell to 7 per cent. In a full hospital patients were constantly being reinfected. The carrier stage of scarlet fever he regarded as only a short one. No return cases of scarlet fever had been received.

Dr. JOHN FREEMAN said he would extend the term "carrier" to cover many other common ailments of a microbic nature. Whilst phthisis was generally included amongst diseases spread by carriers, he thought gonorrhœa should be placed in the same category. A woman with chronic gonorrhœa might show no clinical signs of the disease, but might nevertheless communicate it in an acute form by sexual intercourse. Again, a man with very septic gums might transfer the trouble to another; whilst streptococcal migration to other persons might cause a variety of far-from-negligible troubles, such as tonsillitis, laryngitis, sinusitis, impetigo, and, secondarily, rheumatism, asthma, anæmia, toxæmia. One of the things that might embarrass those who gave prophylactic catarrhal vaccine was the lighting-up of some septic focus which previously had not been obvious. All people were carriers more or less, and the bulk of disease was spread in this way.

Discussion.

Sir JOHN BROADBENT said he had hoped to hear how to cure carriers of diphtheria, scarlet fever, and meningococcal diseases, but it must be admitted that not much advance had been made in those respects. Carriers were much more numerous and virulent in times of epidemic than at other times. Scarlet fever carriers presented a very difficult problem. In 90 per cent. of cases admitted to hospital there was no history of infection, and it was difficult to know how the disease had been acquired; had the patients come into contact with cases which had not been diagnosed? Scarlet fever could be conveyed a long time after desquamation ceased, and when a case went out of hospital it was impossible to be sure it would not be a carrier. He did not know how to deal with meningococcal carriers.

Mr. ZACHARY COPE thought that it was justifiable to remove the gall-bladder of people who were spreading typhoid owing to its infection; especially as, in most of those cases, gall-stones were present. He agreed that the method of intubation practised by Vincent Lyon could first be tried.

Dr. P. R. DODWELL spoke of the success in some schools under the London County Council of a campaign of active immunisation among the children.

Dr. V. S. HODSON referred to the elaborate measures that were taken to lessen the incidence of diseases in the days before microbes were causally connected with them. Many of these precautions had since been relaxed and attention was so much concentrated on bacilli that useful means of prevention were apt to be neglected.

Dr. ANTHONY FEILING asked whether there was any effective medical treatment of a typhoid carrier who rapidly manufactured gall-stones. In one case a man of 23 took hexamine grs. 100 three times a day and developed a second attack of acute cholecystitis.—Dr. HOPE CARLTON spoke of the relationship of scarlet fever and burns in children.—Dr. WARREN CROWE asked for the proofs that scarlet fever was due to a streptococcus.

Dr. MCCARTNEY replied. The parasite and the host, he said, must always be considered together. Also the size of the dose was very important; very few people could withstand any disease if the dose was sufficiently massive. Whenever beds were close together there was always the danger of persistent reinfection. In typhoid carriers removal of the gall-bladder did not necessarily remove infection. He considered that there was ample evidence that scarlet fever was due to a streptococcus.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.

AT a meeting of this Society on March 1st Dr. DONALD HALL, the President, in the chair, a lecture on the Rôle of

Radium in Treatment of Cancer of the Breast and Tongue

was given by Mr. DUNCAN FITZWILLIAMS. One of the changes of the present day, he said, was the replacement of surgery by the use of radium in areas where it could be applied. In the tongue, radium has largely replaced the knife among surgeons who understood its use. Among the methods of applying radium was the insertion of seeds of glass containing radium emanations. These seeds were planted into the tissues and left there; the radium emanation diminished gradually and the glass capsule remained. A drawback to this method was that if it was used in a septic cavity such as the mouth, sepsis might supervene, so that the capsule could not be found in the œdematous tissue. A better method consisted

f the insertion of metal containers with a piece of ne silk attached to them so that they could be ithdrawn after a certain time; an instrument fter the manner of a trocar and cannula had been evised for the introduction of these seeds. This nethod of using radium was rather new, and it was oo soon to say whether it would hold its own, but uperficial growths disappeared as if by magic when reated in this way. Alternatively, needles conaining radium could be employed. They were of arying lengths and were made of platinum 0·5 mm. hick, so as to screen off injurious rays from the tissues. hey should contain 0·2 to 0·5 mg. of radium, and the ost useful length, he thought, was one of two inches. he needles should be left in place for a week or ten ays. Yet another method was to use tubes conaining about 50 mg. of radium, heavily screened. hese tubes were useful in some cases of carcinoma f the cervix. It was an inefficient method of treating ancer to place large doses in the centre of the growth here the cells were degenerating and harmless; it as much better to surround the growth with radium eedles so as to deal with the actively growing edge. he last method of using radium was by tubes or laques, either of the metal itself or emanations, which ere placed upon the skin. He had never obtained ood results from this method in large growths, but was a very good way of dealing with small supercial growths, such as rodent ulcers and epitheliomata f the lips.

In considering cancer of the breast, Mr. Fitzwilliams ointed out that only extrathoracic carcinoma could e treated effectively. If the cancer cells had already ained the interior of the chest, the patient would robably die of internal metastases, however widely ie original growth was removed. In primary arcinoma of the breast the knife was far superior radium in the early stages. Only in atrophic ases, in those which were unsuitable for operations nd in encephaloid cases, was radium to be recomended. The main rôle of radium was to deal with ie external metastases, and these could be treated ith the certainty of cure.

In the tongue, said Mr. Fitzwilliams in conclusion, ie disease was superficially local, but penetrated very eeply; failure to realise this depth of penetration as the cause of local recurrence after operation. eeds or needles would cause the growth in the ongue to disappear, but left a very suspicious ardness behind. For the glands in the neck blocksection, combined with the use of radium, was the est form of treatment. He strongly recommended ie use of lead in combination with radium.

DONATIONS AND BEQUESTS.—Among other bequests e late Mr. Charles Ward, J.P., of Blackpool and Oldham, ft £1000 to the Oldham Royal Infirmary for the endowent of a bed.—Mrs. Harriett Mansfield, Bristol, left £500 ch to the Bristol General Hospital and the Bristol Royal firmary, and £1000 to Muller's Orphanage, Ashley Down.—rs. Amelia Pickup, of the Towers, Hightown, Liverpool, sides other bequests left £1000 to the Blackburn Infirmary r a "James Pickup Cot," and £100 to the Liverpool aternity Hospital—Lady Hudson has made a donation of 000 to Westminster Hospital for the perpetual endowment a ward in memory of the late Sir Robert Arundell Hudson, easurer of the hospital from 1921 until 1927.—Mr. William ving Armstrong, of Hexham, Northumberland, left £1000 ch to the Monkwearmouth and Southwick Hospital, the nderland Royal Hospital, and the Hexham Memorial ospital.—Miss Cecilia Brough, of Ardmere, Dundee, left 000 to the Dundee Royal Infirmary, and £1000 each to e Royal Victoria Hospital, Dundee, and the Royal Dundee stitution for the Blind—each subject to certain life terests.—Under the will of the late Colonel Henry Doughty, rmerly a shipowner of Hartlepool and Harrogate, an itial distribution of £100,000, part of the residual estate, s been made to 20 charitable and philanthropic instituns, and the two hospitals and the Hospital Trust Fund the Hartlepools receive £5000 each; British Legion, 0,000; King Edward's Hospital Fund, £8000; the Port Hull Orphanage, £6000; Dr. Barnardo's Homes, £5000.—. Arthur Smith Graham, of Great Ambrook, Totnes, evon, left £40,000 for charities, and of this sum St. nstan's Hostel for Blinded Sailors and Soldiers will eive one-fourth part.

Reviews and Notices of Books.

THE ABDOMINAL SURGERY OF CHILDREN.

By L. E. BARRINGTON-WARD, Ch.M., F.R.C.S., Surgeon, Hospital for Sick Children, Great Ormond-street; Senior Surgeon, Royal Northern Hospital. London: Humphrey Milford, Oxford University Press. 1928. Pp. 283. 15*s*.

CHILDREN as surgical patients present special problems of their own, and the general surgeon will be glad to have the advice of a specialist in this branch put at his disposal in attractive form. The chapter on general principles is especially good, and while certain of the recommendations for treatment may not receive unanimous endorsement, this does not mean that the author has not reasons for his views. But sometimes more exact guidance is needed. What the reader looks for, and particularly the operating surgeon, in a monograph by a specialist is precise directions to assist him in the technical difficulties he meets. For example, how best to separate the very thin sac of a congenital hernia, by what method to replace an imperfectly descended testicle into the abdomen, how to perform an enterostomy for ileus and when to close it. The lack of detailed information is partly redressed by the good bibliography at the end of each chapter, but many readers would have welcomed a little digest of the teachings and experiences. Everybody will not agree with the author that the pampiniform plexus should be divided or the testicle of a child removed when it cannot be brought down into the scrotum; nor does it seem good advice to say that the size of the incision in acute appendicitis does not matter. It also makes for clearer and more accurate work to search for the collapsed rather than to follow along the distended coils in acute intestinal obstruction. While this much may be said by way of caution to the reader, there is ample evidence throughout the book of the author's large experience and close observation. For example, such useful information as why it is wrong to aspirate a hydrocele, and how abdominal puncture may be used for the diagnosis of pneumococcal peritonitis, is summarised valuably. The book is a creditable addition to an excellent series of monographs of reasonable size from the Oxford University Press, and may be confidently recommended.

FRACTURES IN GENERAL PRACTICE.

Traitement des Fractures par le Praticien. By Dr. ETIENNE, Professeur agrégé chargé du Cours de Pathologie externe à la Faculté de Médecine de Montpellier. Paris: Masson et Cie. 1927. Pp. 194. Fr.16.

THE same causes are at work in France as in England to increase the number and gravity of cases of fracture, and as Dr. Jeanbrau says in a preface to Dr. Etienne's little book, at any moment the general practitioner may find himself urgently called upon to treat such injuries. In particular this book is intended for the country doctor, who has to decide upon and apply immediate treatment, without radiographs, special apparatus, or skilled assistance, relying upon his own wits and manual skill. In such a small work it is manifestly impossible to attempt to do more than describe typical injuries and their typical treatment, and this we think Dr. Etienne has done in a manner worthy of the historic school once adorned by Rabelais.

He gives as general indications of treatment the following three rules: first, keep the patient alive by combating serious complications, such as pneumonia, damage to soft parts, or urinary infection; secondly, restore the functions of the injured limb; and, lastly, make sure of firm union. Dr. Etienne is not an advocate of immediate reduction in all cases, at all costs, but he prefers in some cases, such as

fractures of the lower end of the humerus, to proceed gradually, and even to wait several days before completing reduction. As he says nothing of anæsthetics in this connexion, it may be that this is in some sort a counsel of necessity and not of choice. The method of treating fractures of the leg and ankle, which is known in France as that of Delbet, deserves the attention which Dr. Jeanbrau calls to it in the preface. This method combines weight extension in the first 48 hours while the plaster is setting, with ambulant treatment on crutches after the first three days. The details of the application of the plaster and of the extension and of the instruction of the patient in walking are clearly described. Hardly enough stress is laid upon the importance of complete reduction and replacement of the foot in its normal position in cases of Pott's fracture—here as usual with French writers, called Dupuytren's. Without the help of X rays, however, it will be a matter of doubt and difficulty for the surgeon to assure himself and his patient that the reduction is complete and the prospect of full restoration of function sure. Moreover, unless great attention is given to detail and the instructions very closely followed we fear that the practitioner, inexperienced in such treatment, may find that the ambulant method leads to disaster as regards function.

The 144 outline drawings with which the book is illustrated are clear and helpful, and the methods of treatment recommended are as up to date as the presumed circumstances would allow.

HEART AND ATHLETICS.

By Dr. FELIX DEUTSCH, Privatdocent in Internal Medicine at the University of Vienna; and Dr. EMIL KAUF, Assistant at the "Heart Station" in Vienna. English translation by LOUIS M. WARFIELD, A.B., M.D. London: Henry Kimpton. 1927. Pp. 187. 10*s.* 6*d.*

THAT athletics are responsible for the production of certain forms of heart disease is one of those widely prevalent ideas which are based on general impressions rather than on accumulated facts. When one comes to inquire into the foundation of those impressions it is surprising to find how scanty are the accurate observations on the subject in the English and American literature, and this alone is sufficient to justify Dr. Warfield's translation of the work by Drs. Deutsch and Kauf. The authors have had at their disposal a plentiful supply of material, a supply which, as regards swimmers at any rate, must be almost unique, since the Austrian Swimming Society made it obligatory for all of its members to be examined at the "Heart Station" in Vienna. Attention has been concentrated chiefly on the question of cardiac enlargement, and this fact leads one to make two criticisms of the methods employed. In the first place, is the transverse diameter of the cardiac shadow an adequate index of cardiac enlargement? And secondly, are there not other definitely measurable phenomena which may signify impairment of the cardiac function even in the absence of enlargement?

The material is divided into two main groups: (1) those who take exercise for pleasure, and (2) those who go in for competitive athletics. In the first group there is no evidence that athletics produce cardiac enlargement over and above that which might be expected to be associated with the general improvement in physique. Even in the second group the majority of the individuals studied have hearts of normal size, but in a certain percentage there is definite evidence of abnormal cardiac development. This percentage varies for different types of sport, being highest in rowing. Ski-ing, cycling, swimming, and wrestling come next; it is surprising that running comes low down on the list. The authors consider that emotional factors play an important part in determining cardiac enlargement, but the evidence they produce in support of this opinion is inadequate. An interesting chapter is devoted to the variation in size of the heart, recorded in particular cases, during the course of training, and to the criteria employed for deciding whether training should be allowed to proceed. Though many of the observations on which this book is based are of undoubted importance, some of the deductions from them fail to carry conviction. More evidence on the subject should be collected from various countries.

CHEMOTHERAPY AND SYPHILIS.

Principles and Practice of Chemotherapy. With special reference to the Specific and General Treatment of Syphilis. By JOHN A. KOLMER, M.D., Dr.P.H., D.Sc. (Hon.), Professor of Pathology and Bacteriology in the Graduate School of Medicine of the University of Pennsylvania; Member of the Research Institute for Cutaneous Medicine. London and Philadelphia: W. B. Saunders Company. Pp. 1106. 55*s.*

THIS monograph is based on Prof. Kolmer's book entitled "Infection, Immunity, and Specific Therapy," which he has enlarged and rewritten.

The author begins with a section on the principles of chemotherapy and traces its history back to the discovery of mercury as an antisyphilitic agent in about the year 1500. He then discusses at some length the chemotherapy of various types of disease before passing to the consideration of syphilis; the pharmacology and toxicology of antisyphilitic medicaments and the methods of their administration are dealt with in great, even too great, detail. For example, in the single section, where the technique is described for venous puncture, intramuscular and subcutaneous injections, spinal, cistern, and ventricular puncture and injection, there are some 40 illustrations, many of which are very similar one to another and quite redundant.

More than half the volume is taken up with experimental work on rabbits and guinea-pigs, inoculated with syphilis or other protozoan diseases in relationship to chemotherapy. Various drugs, well and less well known have been employed, and an enormous amount of painstaking work has obviously been done. Experimental work with silver arsphenamin showed a great variation in the spirocheticidal power of various batches of the preparation, but seemed to give a higher therapeutic index than arsphenamin. Arsphenamins of copper, gold, and platinum were found to be more powerfully bactericidal than arsphenamin, but less than silver salvarsan. Prof. Kolmer believes that in syphilis after each injection of salvarsan or neosalvarsan, spirochætes are destroyed 24 to 48 hours after injection "by the therapeutically active oxidation or reduction products, followed by the development of some immunity principles engendered by the antigenic substances released from the destroyed spirochætes. According to his theory these immune substances at least aid in holding the activity of spirochætes in check or latency, if they are not actually destructive for them. He shows experimentally that by giving subcurative doses of salvarsan and neosalvarsan, spirochætes can be rendered resistant to these substances, both in vivo and in vitro. This has been known for some time by syphilologists in active practice and gives the basis of therapy by repeated large-sized doses of salvarsan. Dr. Kolmer found mercury compounds to be much less spirochæticidal than the organic arsenic products. As regards bismuth administration, he holds that the toxicity depends not only on the percentage of bismuth in a preparation, but also on the speed with which it is absorbed. French observers have been emphatic as to the dangers of the intravenous administration of bismuth. Dr. Kolmer gives, as complications after intravenous bismuth, dyspnœa, cough, and thoracic oppression. Jarisch-Herxheimer reactions are dealt with fully, and the grave risk of starting to treat tertiary lesions with large doses of salvarsan or neosalvarsan is noted.

The author's treatment of primary and secondary syphilis is much more intensive than is usual in this country, since he gives, to begin with, three *daily*

ccessive doses of 0·6 g. of a 914 preparation followed
r six more injections of 0·9 g. at the rate of two a
eek. His treatment of later syphilis is more in
cordance with European methods, and his comments
the importance of regarding the old syphilitic case,
th persistently positive Wassermann, as an imper-
ctly cured case, and therefore a potential menace to
mself and the offspring, will give satisfaction to the
actical syphilologist. Part of his antenatal treat-
ent of a woman with a positive Wassermann reaction,
ensure a healthy fœtus, would not meet with
proval in this country, since Dr. Kolmer is an
vocate for inunction of mercury thrice weekly, for
least a month, preferably longer. This mode of
atment is, in our opinion, unnecessarily tiresome
mpared with any result gained; but the author's
her recommendations as to intravenous injections
614 and intramuscular injections of bismuth during
egnancy are in accordance with European methods.
ere is no reference, anywhere in this book, to the
e of sulphur as a preventive of toxæmia—either in
e form of contramine or of sodium thiosulphate.
e use of a glucose drink before the administration of
senical derivatives is evidently not in vogue in
nerica. An undue amount of space is occupied with
scriptions of alternative methods of administration
mercury and iodides.

The book is a strange combination of a review of
perimental laboratory methods with a manual of
nical instruction suited to those who have not even
elementary knowledge of the modern technique in
philis. The author has included all the recom-
nded drugs and methods of treatment, including
n-specific protein therapy and malarial inoculation,
d his bibliography is enormous. But it is difficult
see for what class of medical practitioner the book
s been written.

RECASTING EPIDEMICS.

Climate and Disease Incidence in India: Fore-casting Epidemics. Being the twenty-ninth Robert Boyle Lecture. By Sir LEONARD ROGERS, C.I.E., M.D., F.R.C.P., F.R.C.S., F.R.S. London: Humphrey Milford, Oxford University Press. 1927. Pp. 39. 1*s.*

THIS little booklet embodies the Robert Boyle lecture
1927 which threw light, from the special angle of
e author's experience in India, on the vexed subject
the epidemic constitution. The varied climate of
dia presents unique opportunities for studying the
ect of meteorological factors on different diseases.
e lecturer found that leprosy, rainfall, and humidity
clined steadily from east to west up the Gangetic
lley, whilst the unfavourable effect of rain-bearing
nds on tuberculosis was amply confirmed. Small-
x showed a marked decline during the south-west
nsoon, but the essential factor seemed to be the
solute humidity of the atmosphere. The same
tor plays a large part, Sir Leonard Rogers considers,
the incidence of cholera, and he points out that,
hough variations in the weather are outside the
here of preventive medicine, much can be done by
ncentrating sanitary armies at the points of danger
these can be forecast. All who are concerned with
idemiology or with the prevention of disease in
dia will find much to interest them in the lecture.

UBERCULOSIS.

Contributions to the Study of Tuberculosis. By Research Department, National Jewish Hospital at Denver. Vol. VII.

THIS volume reflects credit on the director and his
lleagues. The report contains a mass of material,
vided into three sections. The introductory section
chiefly biographical and consists of addresses given
well-known pioneers of medicine. The second
ction is devoted entirely to laboratory research.
e third deals with clinical contributions, such as
e surgery of pulmonary tuberculosis, tuberculin,
cidental pneumothorax, the treatment of bronchial asthma, and essays on diet. The research section gives a number of original communications reprinted from the *American Review of Tuberculosis*, on the variability of the localisation of tuberculosis in the organs of different animals; several papers on tissue reactions to *B. tuberculosis*, and also some work on the cytomorphology of the tubercle bacillus. The work on the variability of localisation of tuberculous lesions in various animals is of particular interest. Here it is shown that the extent of the distribution of tubercle bacilli to the various organs is alone insufficient to explain the lesions. In addition to the ability of the cells of the histological tubercle to destroy the bacillus, changes in oxygen tension in tuberculous foci are shown to be sufficient to change a quiescent focus into progressive disease.

IMMORTALITY.

By I. HARRIS, M.D. London: Williams and Norgate, Ltd. 1927. Pp. 68. 2*s.* 6*d.*

THIS book deals with man's place in the universe and the meaning and goal of existence, and its number of pages indicates the fragmentary character to which the author confesses in the preface. But his attempt to describe a momentary glance or fleeting impression of a realm difficult to conceive is a brave one. Assuming that the opinion is gaining ground that the different elements are compounds of one really elementary body, and that at the basis of all diversity there is unity, he regards existence as a uniform thing, our phenomenal world being the realisation of different states of matter, while death, or complete dormancy, is the condition where the phenomenal world is non-existent, all diversity being swallowed up in uniformity. On the subjects of individuality and the universe as a self-creating and self-regulating entity he finds that individual life can be accounted for only by universal life and momentary existence by eternal existence. A chapter on religion is an endeavour to find a creed in harmony with modern progress, and the riddle of immortality is left unsolved in a final chapter.

PROHIBITION.

Its Economic and Industrial Aspects. By HERMAN FELDMAN, Ph.D., Assistant Professor of Industrial Relations, Dartmouth College. London and New York: D. Appleton and Co. 1928. Pp. 415. 7*s.* 6*d.*

IT is as difficult for anyone in this country to get a sure idea of the effects of prohibition in the United States as it is to find out exactly what has happened in Russia; most commentaries on both situations are confessedly biased one way or the other, and any which seem objective and neutral in outlook are naturally suspect. But Dr. Feldman says that his account is no more than a summary of the most exact facts which he has been able to ascertain, and a reading of his book fails to suggest any other attitude on his part. It is then prima facie worth attention. He limits himself to the economic and industrial aspects of the Volstead Act, and moral, political, and social questions are left on one side. Prohibition meant at the first a considerable loss in property to the brewing and distilling trade, some loss to farmers who grew barley and hops, and an unimportant loss in taxation. These were temporary. Taking a longer view, he finds that employers are overwhelmingly favourable to prohibition as it affects production and business. The money formerly spent on drink now goes to other things, and there is a general agreement that the standard of living of the worker is much higher. There is no doubt that Dr. Feldman thinks that the balance works out strongly in favour of prohibition. But he is uneasy about the future. Prohibition has certainly not stopped drinking, and probably never will stop it entirely, and since 1920 the statistics for alcoholic deaths, alcoholic destitution, and arrests for drunkenness have all shown an upward direction.

MEMORIAL FUND TO SIR DAWSON WILLIAMS.

THE following is a list of the first subscribers to the Memorial Fund in honour of Sir Dawson Williams. It was rightly decided that the movement for a testimonial, which was started in the week before his death, should continue, and that the resulting Fund should be employed in the institution of a memorial to him connected in some intimate and apt manner with the advancement of medicine. The Fund remains open for a time in order that answers to the appeal may be awaited from medical men resident abroad.

LIST OF SUBSCRIBERS.

A.—Rt. Hon. Christopher Addison, F.R.C.S.; Dr. T. Dyke Acland; Dr. E. D. Adrian; Dr. G. A. Allan; Dr. J Ford Anderson; Sir Hugh Anderson, M.D.; Dr. H. Russell Andrews; Dr. J. A. Arkwright.

B.—Dr. F. J. Baildon; Dr. Andrew Balfour; Sir C. A. Ballance; Sir H. A. Ballance; Sir Gilbert Barling, Bt., F.R.C.S.; Sir Thomas Barlow, Bt., M.D.; Mr. H. Norman Barnett, F.R.C.S.; Sir James Barr; Lady Barrett, M.D.; Dr. H. Batty-Shaw; Dr. E. Clifford Beale; Sir George Beatson, M.D.; Dr. T. Izod Bennett; Sir Wm. Bennett, F.R.C.S.; Dr. Comyns Berkeley; Sir James Berry, F.R.C.S.; Dr. H. S. Birkett (Montreal); Dr. A. D. Blackader (Montreal); Prof. Blair Bell; Sir John Bland-Sutton, Bt., F.R.C.S.; Sir Robert Bolam, M.D.; Dr. J. W. Bone; Mr. Victor Bonney, F.R.C.S.; Dr. H. B. Brackenbury; Prof. J. B. Bradbury; Sir J. Rose Bradford, M.D.; Sir Byrom Bramwell, M.D.; Dr. Edwin Bramwell; Dr. H. C. Bristowe; Mr. W. Rowley Bristowe, F.R.C.S.; Sir J. F. Broadbent, Bt., M.D.; Sir G. S. Buchanan, M.D.; Dr. R. M. Buchanan; Dr. R. C. Buist; Prof. A. H. Burgess, F.R.C.S.; Dr. Judson S. Bury; Mr. H. B. Butler, F.R.C.S.; Dr. C. Buttar; Sir Farquhar Buzzard, M.D.

C.—Dr. F. Foord Caiger; Sir Hector Cameron, M.D.; Mr. Rock Carling, F.R.C.S.; Prof. E. P. Cathcart; Mr. G. A. Carter, F.R.C.S.; Dr. George Cathcart; Dr. E. J. Cave; Dr. A. K. Chalmers; Sir Francis Champneys, Bt., M.D.; Dr. Arnold Chaplin; Sir Lenthal Cheatle, F.R.C.S.; Prof. C. C. Choyce; Prof. A. J. Clark; Mr. Ernest Clarke, F.R.C.S.; Dr. F. W. Cock; Dr. Denis J. Coffey; Mr. William Coates, F.R.C.S.; Mr. L. Colledge, F.R.C.S.; Dr. W. T. Collier; Dr. John D. Comrie, Mr. Russell Coombe, F.R.C.S.; Dr. D. E. Core; Dr. Alfred Cox; Sir Maurice Craig, M.D.; Sir James Craig, M.D.; Prof. Winifred Cullis; Prof. Harvey Cushing (Massachusetts).

D.—Dr. H. Guy Dain; Dr. H. H. Dale; Lord Dawson of Penn, M.D.; Dr. John D'Ewart; Dr. W. E. Dixon; Dr. A. Donald; Mr. Malcolm Donaldson, F.R.C.S.; Prof. Denis Donovan; Dr. J. R. Drever; Sir J. Dundas-Grant, F.R.C.S.; Dr. T. P. Dunhill.

E.—Dr. G. Leslie Eastes; Mr. W. McAdam Eccles, F.R.C.S.; Prof. T. R. Elliott; Dr. John Eyre.

F.—Dr. J. S. Fairbairn; Mr. H. Fairbank, F.R.C.S.; Dr. John Fawcett; Dr. A. Feiling; Lt.-Gen. Sir Matthew Fell; Dr. Freeland Fergus; Mr. E. F. Finch, F.R.C.S.; Prof. Leonard Findlay; Dr. William Fletcher; Dr. H. Morley Fletcher; Dr. E. Rowland Fothergill; Dr. T. F. Fox; Prof. John Fraser; Dr. Thomas Fraser (Aberdeen).

G.—Prof. G. E. Gask, F.R.C.S.; Dr. J. F. Gaskell; Sir Henry Gauvain, F.R.C.S.; Mr. H. D. Gillies, F.R.C.S.; Prof. John Glaister; Dr. E. W. Goodall; Dr. G. W. Goodhart; Dr. William Gordon (Exeter); Dr. Mervyn Gordon; Dr. G. S. Graham-Smith; Sir Henry Gray, F.R.C.S. (Montreal); Prof. Major Greenwood; Dr. F. W. W. Griffin.

H.—Dr. J. S. Haldane; Sir William Hale-White, M.D.; Prof. A. J. Hall; Dr. F. de Havilland Hall; Dr. Donald Hall; Mr. W. Sampson Handley, F.R.C.S.; Mr. N. Bishop Harman, F.R.C.S.; Col. L. W. Harrison, R.A.M.C.; Prof. W. F. Haslam; Dr. C. O. Hawthorne; Dr. Kenneth Hay; Dr. R. Wallace Henry; Prof. A. V. Hill; Dr. G. B. Hillman; Mr. R. G. Hogarth, F.R.C.S.; Mr. Eardley Holland, F.R.C.S.; Sir Thomas Horder, Bt., M.D.; Dr. N. G. Horner; Dr. James Hudson (Newcastle-on-Tyne); Dr. F. Howard Humphris; Dr. J. B. Hurry; Dr. A. F. Hurst; Dr. Gordon Holmes; Mr. Thurstan Holland, Ch.M.; Sir Alexander Houston, M.B.; Dr. R. Hutchison.

J.—Mr. R. R. James, F.R.C.S.; Mr. F. A. Jeans, F.R.C.S.; Mr. Geoffrey Jefferson, F.R.C.S.; Sir Robert Jones, Bt., F.R.C.S.

K.—Prof. W. W. Keen (Philadelphia); Sir Arthur Keith, F.R.C.S.; Dr. J. R. Keith; Dr. Brown Kelly; Mr. Richard Kelly; Sir Alfred Keogh, F.R.C.S.

L.—Sir W. Arbuthnot Lane, Bt., F.R.C.S.; Dr. W. Langdon-Brown; Dr. R. Langdon-Down; Dr. E. Kaye Le Fleming; Mr. Hugh Lett, F.R.C.S.; Sir Thomas Lewis, M.D.; Mr. Muirhead Little, F.R.C.S.; Dr. G. Carmichael Low; Mr. Warren Low, F.R.C.S.; Sir Richard Luce, M.P., F.R.C.S.; Dr. A. Lyndon.

M.—Sir Donald MacAlister of Tarbert, Bt., M.D.; Dr. J. A. Macdonald; Dr. J. Sinclair McGowan; Prof. Ashley W. Mackintosh; Prof. Louise McIlroy; Col. D. J. Mackintosh, A.M.S.; Dr. John Macintyre; Sir Leslie Mackenzie; Dr. L. G. J. Mackey; Sir Ewen Maclean, M.D.; Dr. John McNamara; Dr. J. W. McNee; Sir Andrew Macphail, M.D. (Montrea Dr. A. D. Macpherson; Sir G. H. Makins, F.R.C.S Dr. A. Manknell; Dr. J. S. Manson; Dr. P. Manson-Bah Prof. E. Mellanby; Dr. Stanley Melville; Dr. G. W. Miller; R. M. Miller; Sir William Milligan, M.D.; Prof. T. H. Milro Dr. Gustave Monod (Paris); Prof. T. R. Monro; Mr. K. Monsarrat, F.R.C.S.; Sir J. W. Moore, M.D.; Dr. T. Moorhead; Mr. F. Waugh, F.R.C.S Mr. A. E. Webb-Johnson, F.R.C.S.; Dr. F. Parkes Webe Sir William Wheeler, F.R.C.S.I.; Sir William Whitla, M.D Prof. D. P. D. Wilkie; Dr. W. Camac Wilkinson; Mr. Wilkinson, F.R.C.S.; Mr. R. J. Willan, F.R.C.S.; D Leonard Williams; Dr. Claude Wilson; Dr. Cartwright Woo Mr. Musgrave Woodman, F.R.C.S.; Dr. A. S. Woodwar Sir Robert Woods, F.R.C.S.I.; Sir Almroth Wright; Dr. Ellis Wynter.

Y.—Dr. L. R. Yealland; Prof. Archibald Young.

All subscribers who wish to be included in the futu lists which will be published are invited to sen their contributions at once to Sir StClair Thomso 64, Wimpole-street, London, W., to whom cheque should be made payable, while the envelope shou be marked "Dawson Williams Testimonial."

KING'S COLLEGE HOSPITAL.—It was reported the annual court of governors that a ward set free by t removal of the Massage School to a neighbouring house being used as a substitute for any ward that is being clean and renovated. It is hoped presently to erect two, perhaps three wards for paying patients. The number treatments given in the Physical Treatment Departme has increased from 40,000 in 1921 to over 81,000 in 1927.

CHILDREN'S HOSPITALS.—The King and Quee have consented to perform the opening ceremony in Ma next of the new Princess Louise Kensington Hospital f Children. Their Majesties have, however, made it a cond tion that the building shall by then be free of debt. T amount still needed is £9250, but £1000 has been promise by the King's Fund, and £500 from another source, bot conditionally upon the full amount being raised.—T annual report of Birmingham Children's Hospital show that last year the total number of children admitted w 5274, nearly 1000 more than in 1926; the average dail number of inmates was 145. To relieve the growing pressu upon the hospital it is proposed to add two wards of abo 40 more beds at a cost of £10,000. A speech defects clin was begun in July last, and the private ward continued t be a successful adjunct.

THE LANCET.

LONDON: SATURDAY, MARCH 17, 1928.

PAINLESS CHILDBIRTH.

THE due provision of anæsthesia during labour is ot so simple as it appears at first sight, or to those ho have not considered the problem as it affects he motherhood of the nation as a whole. On one spect only of the subject was complete unanimity isplayed during the discussion recently held at the oyal Society of Medicine.[1] That unanimity was xpressed regarding the desirability of using anæsietics for confinement cases. It was pointed out, ith undoubted truth, that it would be a national dvantage for women to be rid of the traditional ar of the pains of childbirth, and for them to know iat the process might be made at least as painless ; any ordinary surgical operation. Too many omen are deterred from motherhood, or their safety threatened, by that fear of pain which, as Dr. ARDLEY HOLLAND pointed out, is instilled into eir minds from childhood upwards by words in the ook of Common Prayer, if not from other sources so. A new tradition of painless labour should be opagated. And it must be founded on fact. It is t enough to show that a confinement can always freed from any grave amount of pain. It must tually be made free. Of objections to the use of æsthetics during labour those based on religious ounds are now happily regarded as dead and buried. ater opposition has depended on the belief that the æsthetics delayed labour, or were injurious to the other or the child, or to both. The truth is that, operly employed, anæsthetics need never delay d can actually expedite the child-bearing process. r there is a stage of that process when the patient ay do all she can to retard the oncoming head owing the agony of pain which its advance is causing. algesia or anæsthesia at this time will, as was inted out at the discussion, lead actually to a minution of the time spent on giving birth to the ild. Though it is true that all anæsthetics have perimentally been shown to have the power to lay the contractions of the uterus, there is much ference between their use in order to demonstrate is fact in the laboratory and their skilful clinical ployment. When properly used anæsthetics can olish pain at a normal confinement without delay- progress. This proper use implies a method by ich a state of analgesia, rather than anæsthesia, kept up intermittently throughout the greater rt of the time. Between the "pains" the patient mbers, at the "pains" she inhales anæsthetic ough to keep her free from pain, and this state is shed to true surgical anæsthesia only at the critical t of the expulsive stage, or at the accoucheur's uest.

There is more than one way of obtaining this ired state of analgesia and anæsthesia. It seems be admitted widely that the ideal is reached by skilled employment of nitrous oxide and oxygen, most ideals are difficult of attainment, and this o exception. In fact, it may be said with truth that the use of nitrous oxide and oxygen for confinements is impracticable in the vast majority of cases. Certainly it can be employed in institutions, nursing homes and hospitals, and in private houses if special arrangements can be made, but there must be a narrow bed and there must be cumbersome apparatus. Given these and a skilled anæsthetist prepared to devote unlimited time to the case, then a normal confinement can be conducted so as to save all pain and so as to leave the patient less disturbed by the process than is possible in any other circumstances. Nitrous oxide is, of course, a non-toxic anæsthetic; the metabolism of mother and child is entirely unaffected, and the uterine contractions of labour are neither delayed nor diminished. The same advantages cannot, all of them, be claimed for the anæsthetic most commonly employed for confinements in Great Britain—namely, chloroform. Notwithstanding its defects, however, most of the speakers at the discussion to which we have referred were prepared to defend and advocate its employment. This may at first sight seem strange when we remember the almost general condemnation of chloroform as a routine anæsthetic for operations nowadays. Nevertheless the apparent contradiction is fully justified. The proper use of chloroform in midwifery is very different from its use for surgical operations. The conditions are different and the object aimed at is different. To begin with, there is in the woman in labour an entire absence of that psychic danger which arises from fear of taking the anæsthetic. The woman in labour, so far from being afraid of an anæsthetic, is crying out for one. This rules out in her case that formidable and not entirely explicable risk which is involved in the induction of anæsthesia by chloroform in a patient who is fearful of it. Again, the drug is used during labour, when it is used expertly, in such a way that a condition of little more than analgesia is produced during the attacks of pain. It is entirely withheld in the intervals, and surgical anæsthesia is produced, if at all, only when the head is passing over the perineum. The accumulated evidence of years supports the contention that in skilled hands chloroform can be more safely used in confinements than in general surgery. When abnormal labours or obstetric operations are concerned most anæsthetists, we believe, prefer ether, and assist the case on ordinary surgical lines. The use of twilight sleep as the chief means of avoiding pain does not appear to have many supporters, but a modified use of sedative drugs—chloral, omnopon, morphia, and scopolamine—early in labour is evidently favoured by those best qualified to speak, and is practised in conjunction with anæsthetics. What is known as "synergistic anæsthesia" has not been widely employed in this country. It often involves several intramuscular injections as well as a rectal injection. On a priori grounds the rectum would not usually be selected as a convenient introductory route in the pregnant woman, and it does in fact appear that sometimes there is difficulty in getting the catheter past the fœtal head. Moreover, the patient not infrequently expels the rectal injection. (This was indeed alluded to by one sarcastic speaker as the sole recommendation of the method.) These disadvantages would have to be ignored, of course, if the method were shown to have the great superiority claimed by its American originators, but from their own country there has lately come a well-supported review[2] of "synergistic anæsthesia" which is by no means encouraging. It is here stated that

[1] See THE LANCET, March 10th, p. 498.

[2] Jour. Amer. Med. Assoc., Dec. 17th, 26th, 31st, 1927.

"GWATHMEY and his associates have attempted to develop a method of anæsthesia without an adequate experimental basis; hence they have fallen into errors which could have been avoided, and GWATHMEY has based theories on erroneous views which have been accepted and repeated by other writers." Strong arguments are adduced against the actual occurrence of the synergism described as resulting from the coöperation of morphia and magnesium sulphate and ether in the technique recommended by GWATHMEY, while it is admitted that "the action of morphine on the respiratory centre is synergistic with that of ether and magnesium sulphate, and that numerous deaths have resulted from their combined use."

Whatever be the method of anæsthesia decided on as most generally desirable in obstetrics, the great practical problem in this country still remains unsolved. That problem is how to bring this desired anæsthesia within reach of the great majority of child-bearing women. At the present time a large majority of the children born in England are born under the ægis not of a medical man but of a certified midwife. The midwife has no authority to use, and no training in the use of, anæsthetic drugs in the second stage of labour, although under the rules of the Central Midwives Board she is at liberty to administer sedatives such as morphia, chloral and bromide in the first stage and has received appropriate instruction. Should this arrangement be extended so that these women are trained in some specified safe, simple anæsthetic administration? If that expedient is not resorted to, in what way is the medical profession to answer the demand which it is making—that every child-bearing mother should be relieved of her pain at labour? The problem is a thorny one. There are members of the profession who believe that the use of anæsthetics is already not sufficiently safeguarded, and who would like to see a special diploma instituted to mark out the man who has special skill and knowledge in this department of practice. The mere idea of a midwife using anæsthetics at all would obviously be anathema to those who think thus. We can make no pretence to offering a solution of the problem of supplying adequate anæsthesia for obstetrics in the country at large; but the recognition that a problem exists is the first step towards its solution, and we hope that the questions involved will receive serious attention. They merit it.

LEGAL COMPULSION IN VENEREAL DISEASE TREATMENT.

A RECENT account of venereal disease legislation in Germany touches significantly upon the problem which the Edinburgh Corporation Bill has brought into prominence. Writing on the new German law in the *World's Health* for March, Dr. ROESCHMANN, of Berlin, naturally dwells upon the familiar fact that many patients, either from ignorance or callousness, neglect their treatment before they are completely cured, and thus become liable to dangerous relapses which make them a constant peril to others. On this account, he says, the national insurance institutes in Germany organised in 1916 antivenereal observation stations which exercised a sort of supervision by summoning patients to report until completely cured. The system was voluntary; if the patient ignored the summons, he could not be compelled. The new German law preserves the voluntary principle as far as possible, but reinforces it with compulsion. In future if a patient breaks off his visits his doctor will first ask him to resume treatment. On refusal the doctor will report the case either to the observation station or to the health authorities which in their turn will summon him to resume the course. These two summonses will contain no threat; it is only when the patient refuses to comply with the summons of the health authorities that coercive measures will be taken, involving compulsory treatment and (if necessary) detention in hospital. The change in the law is that the health authorities can enforce compulsion which was not—and still is not—within the competence of the observation stations. Treatment involving serious risk may not be prescribed without the patient's consent. He may choose his own doctor, and the doctor may choose his own method of treatment; treatment of this class of disease is confined to doctors qualified to practise in Germany. The new law abandons compulsion in respect of the police regulation of prostitution, but it allows the competent health authority to require a person suspected of spreading infection to present a medical certificate or to submit to medical examination in an approved hospital. Doctors, as Dr. ROESCHMANN observes, have always tried to obtain voluntary evidence of the source of a new infection and to persuade the person responsible to submit to treatment. In the event of refusal there was, however, no other legal remedy than the cumbrous invocation of Articles 223–4 and 230–1 of the Penal Code which provided penalties for the infliction of bodily injury with or without malice aforethought. This latter step was rarely taken because the person concerned shunned publicity and because the medical profession was bound by its rule of secrecy. Henceforth, says Dr. ROESCHMANN, doctors are free to report sources of infection to the health authorities in Germany, since the employees of the health services are themselves bound to keep professional secrets. Further, he adds, the notification of a case to the health authorities involves no inconvenience to the patient; it is only when the patient refuses to submit to treatment that coercion begins.

These extracts deal with but one aspect of the new law passed in 1927 by the Reichstag and depending in part upon detailed regulations with which the several States of the German Republic have subsequently supplemented the Reich law. The extracts have been selected for their bearing upon the Edinburgh Bill controversy. In that controversy all parties have really but a single purpose—to stamp out venereal disease at the earliest possible moment. Their only difference is as to method. The Bill, say its opponents, relies upon compulsion when the full possibilities of the voluntary system have not yet been exhausted. The general medical practitioner, they say, is not always competent to use modern technique for the detection and treatment of syphilis and gonorrhœa; the Bill will lead to the giving of medical certificates of freedom from infection which will not always be trustworthy. There is a threat, say the opponents of the Bill, to the profession's tradition of secrecy, a danger of abuse of the denunciation of suspected persons. Compulsory notification they continue, might be largely ignored by private practitioners, so that the only persons penalised would be those attending venereal disease centres. The effect of the Bill, they contend, would be to deter the infected person from reporting for treatment or to induce him to give a false name and address to even a greater extent than such persons do already. These arguments are undeniably weighty; it is f

Parliament to say if they overweigh the considerations urged in favour of the Edinburgh experiment. There are plenty of examples of the process by which a progressive movement in public health, tentatively initiated by a local authority, has afterwards been adopted by the Local Government Board or its successor the Ministry of Health. The standard of public health legislation throughout the country is raised by broadening the application of new principles which have been found successful locally.

The first question is whether the voluntary system can eradicate venereal disease in a reasonable period. If the answer is in the affirmative, there is no other question. If it is in the negative and if the voluntary principle is to be reinforced, it is difficult to see what better safeguards can be devised than those in the Edinburgh Bill. Those conditions seem to have been attained in which the Trevethin Committee was prepared to advocate experimental local legislation. Australia has tried compulsion with results which baffle observers at a distance. Edinburgh offers to make the experiment nearer home; her public health record is known and her medical staff is trusted. Parliament has to say whether the experiment shall or shall not be made.

THE PREVALENCE OF RESPIRATORY DISEASES.

ALTHOUGH cancer is the cause of death which attracts most public attention and its proportional share of the gross mortality is large, 11·7 per cent. in 1926, the toll taken by the non-tuberculous diseases of the respiratory system—of which pneumonia and bronchitis are far the most important—is much greater. In 1926 15 per cent. of all deaths were due to diseases of the respiratory system (exclusive of tuberculosis). In his annual report for 1925, Sir GEORGE NEWMAN devoted special attention to the problem of the respiratory diseases. Reviewing the evidence suggesting that some part of this mortality was preventable he wrote as follows:—

"We cannot *prove* in a logical and convincing way that climate, or the pollution of the atmosphere with smoke, dust and other ingredients, are directly murderous, but we know by experience that their presence is inimical to all forms of life, just as we know that sunlight and fresh clean air are favourable to vitality and resistance to infection. Every form of industrial or mechanical contrivance which either prevents or reduces pollution of the atmosphere is a contribution to the public health, and this aspect of the problem calls for the continued and vigilant attention both of authorities and those responsible for commercial concerns. But this is not all. There is needed an increase in the knowledge and practice of healthy living. Much can be done by personal prudence, by cleanliness, by exercise, by correct breathing, by domestic ventilation, and by the practice of individual hygiene."

In this issue we print an interesting study of the data from the statistical point of view by Miss H. M. WOODS, of the London School of Hygiene and Tropical Medicine. In an earlier paper Miss WOODS gave reasons for thinking that the pneumonia of childhood is more sensitive to environmental conditions than that of later ages. Thus she found that the net, or partial, correlation between the death-rate under five from pneumonia and the percentage of the population overcrowded (the data were the statistics of the London boroughs, 1921–23) when the death-rates from pneumonia at ages 45–64 and 65–74 were held constant, was large and positive. On the other hand, the pneumonia death-rate of middle life was only moderately, and that of old age not at all, correlated with the measure of unsatisfactory housing. Her present paper deals with the subject in a more general way, and her account of the statistical difficulties in the way of evaluating the precise influence of such factors as temperature and air pollution upon the rate of mortality will be welcomed by those who have, perhaps, felt some impatience with the hesitancy of statisticians in pronouncing judgment. The evidence collated by Miss WOODS, who rightly gives prominence to the observations of Prof. E. L. COLLIS, plainly strengthens the case from which Dr. STEVENSON and Sir GEORGE NEWMAN have inferred that a large element of the mortality from respiratory diseases is indeed preventable, just as it confirms the view that there is no *one* noxious factor the elimination of which would be effective. Miss WOODS has displayed a reticence, not always observed by students of public health problems who are not members of the medical profession, in discussing the purely medical aspects of the subject. But medical readers will surely endorse the implication of her last paragraph and its relevant quotation from the Chief Medical Officer of the Ministry of Health's report for 1923: "The time has come when the whole question of using isolation hospitals to greater advantage calls for the consideration of local authorities, and it may well be that fuller regard should be paid to patients suffering from respiratory disease." It is to be feared that many victims of pneumonia are not at present receiving that skilled nursing and attention which are the beginning and end of successful treatment.

Annotations.

"Ne quid nimis."

ASTHMA RESEARCH COUNCIL.

FEW problems in medicine present a more fascinating study than that of asthma. During an attack the patient often appears to be in extremis and his sufferings are pitiful to watch; yet shortly afterwards he is in perfect condition and he may even be a successful athlete between his attacks. On seeking a cause we are struck by the variety of conditions which may give rise to an attack. One subject may suffer only at the week-ends, another only at certain seasons of the year. Climate affects some asthmatics but has no effect on others. Some are at their best in a bad London fog. Dust plays an important part, and so sometimes do the emanations from certain animals. Particular articles of food will invariably bring on an attack with some victims, while with others diet seems to make no difference at all. There is a strong neurotic element in many cases and several members of one family may be asthmatics. With such a variety of exciting causes it is obvious that to find any treatment, the basis of which is to remove the cause, will be a matter of considerable complexity, and no one can wonder at the large number of so-called cures on the market. Further, difficult as it is to prevent a recurrence of the asthma, it is usually a simple matter to relieve the symptoms during an attack and the majority of quack medicines aim solely at relieving the bronchial spasm. Amongst the many peculiarities of asthma are the diseases with which it is often associated. A patient may suffer from severe eczema and asthma alternately, another may have epilepsy, urticaria, angio-neurotic œdema, or some other affection, but they usually come separately, so that whilst suffering from eczema he is free from asthma. Sufferers, as a rule, are free from

attacks during pregnancy or during an acute illness, such as enteric fever.

In order to study these problems certain sufferers from asthma have formed an Asthma Research Council and have appointed a Medical Advisory Committee. The Council are anxious for help, especially from sufferers, and an appeal has been sent to the medical press in the hope that doctors may get the support of their asthmatic patients. There can be little doubt that research into these problems will be of substantial value. The personal experiences of a large number of individual asthmatics should provide a wealth of material from which much information may be obtained. Organised research is the only way of investigating the numerous problems presented by asthma and its allied conditions. The Asthma Research Council, in their appeal, suggest a number of lines along which the investigation may proceed, and the phenomena of sensitisation and desensitisation are of special interest. It has been observed that shock of any kind will desensitise some asthmatics for a time and shock therapy has a recognised place in the treatment of asthma. Shock may be induced by an intravenous injection of any foreign protein, and peptone is frequently used, but shock resulting from an accident, such as a brokem leg, frequently renders the patient free from asthma for some time. Desensitisation, in the strict sense of destroying the patient's sensitiveness to some specific substance, is also a matter for careful consideration. It is not known to what degree an immunising substance acts by virtue of being a foreign protein. Tuberculin has been used in the treatment of asthma and good results have been observed in some cases. This gave rise to a belief that tuberculosis was in some way connected with asthma, whereas in all probability the tuberculin acted simply as a non-specific protein—it may be noted that similar results have been obtained by injecting milk. In short, so many methods of treating asthma have been described that no one principle of treatment is recognised, while new "cures" are constantly being advocated. The Asthma Council proposes to investigate the value of these various "cures" and to try to find some scientific basis for building up a rational form of treatment.

The relationship between asthma and certain allied conditions, such as hay-fever and migraine, deserve the promised attention particularly, for, as the cause of asthma in the particular condition was discovered we should also have an explanation for diseases of other sorts. From all of this it will be seen that there is a large field for investigation open to the Council. Our present knowledge of asthma and the many problems associated with it is confused. There is a large quantity of material awaiting investigation, for asthma is a very common condition in its numerous different manifestations. Organised research may yield very helpful results. Those suffering from asthma, to whose attention the movement for self-help will now be brought, can assist by taking an active interest in the movement financially and otherwise, while helping with much of the research that does not require special medical knowledge.

PHYSIOLOGICAL CHOLAGOGUES.

THE hypothesis that there is an entero-hepatic circulation of bile—i.e., that a portion of the bile is absorbed from the intestine and on reaching the liver in the portal vein supplies the material for a further secretion of bile—was suggested in 1868 by M. Schiff, as a result of his experiments on dogs by what he called his "amphibolic" fistula. A large fistulous opening was made between the gall-bladder and the surface of the abdomen without ligature of the common bile-duct, and it was found that the bile flowed externally, unless the cannula in the fistula was closed, in which case it passed into the intestine. The quantity of bile obtained in a given period was always much greater immediately after the bile had been allowed to flow into the intestine than when it was allowed to flow externally. It was also noted that the introduction of bile-salts through a fistula in the duodenum increased the quantity of bile. Views on biliary secretion were profoundly changed however, in 1902, when Bayliss and Starling, by the intravenous injection of secretin free from bile-salts caused a copious secretion of pancreatic juice and doubled the flow of bile from the liver. In 1925 Mellanby [1] showed that bile of adequate reaction introduced into the duodenum of the cat caused a large secretion of pancreatic juice—sometimes lasting three hours—owing to secretin being carried by absorbed bile-salts into the portal vein. He has continued his researches in two sets of experiments chiefly on cats and on rats, which have no gall-bladder. To determine how secretin acts as a cholagogue experiments were made on the effects of intravenous injection of purified secretin, also on its possible destruction in the blood, and the effects of its repeated injection and the effect of clamping the pancreatic vein. Purified secretin acts as a cholagogue, as a secondary effect depending on its action on the pancreas. Secretin acts on the pancreas causing a secretion of pancreatic juice and as a result of this glandular activity metabolic products pass into the portal vein and are carried directly to the liver. These metabolic products from the pancreas excite the biliary activity of the liver and cause an increased secretion of bile. To test whether secretin is the immediate excitant of biliary secretion after injection of bile into the duodenum, acidified bile was injected into the ileum. Bile was rapidly secreted, but there was no flow of pancreatic juice which makes it evident that the liver can secrete bile into the duodenum quite independently of the absorption of secretin into the blood. The experiments show that injection of bile into the duodenum causes a large secretion of pancreatic juice and augments the secretion of bile; a similar injection of bile into the ileum or an intravenous injection of bile salts will augment the flow of bile, but has no effect on pancreatic secretion. The intravenous injection of purified secretin causes a large secretion of pancreatic juice and augments the flow of bile, but secretin's action as a cholagogue is annulled by procedures which prevent the secretion of pancreatic juice. To sum up, bile-salts, free of secretin and absorbed into the blood from the small intestine, act as cholagogues, whilst the action of secretin as a cholagogue is secondary to its action on the pancreas.

TRAVELLING EXPENSES AND INCOME-TAX.

AN editorial article in the *Journal of the American Medical Association* for Feb. 11th indicates that revenue authorities in the United States discriminate against the medical profession by not allowing the right to deduct in the computation of federal income tax travelling expenses incurred in attending the meetings of medical bodies. Other professional men and traders, it is suggested, are allowed to make this deduction. In England it is doubtful whether such travelling expenses would be a permissible deduction. The courts have refused to allow any deduction by a professional man for the cost of his annual subscriptions to professional organisations whereby he keeps himself abreast of the latest developments which affect his calling. No general deduction, it seems, can be made for the cost of equipping a professional library, essential though it may be to a practitioner; but it is possible that the cost of purchasing new editions of essential text-books could properly be deducted under the wear-and-tear provisions which a few years ago were extended from trades to professions. Rules 9 and 10 of the relevant schedule of the Income-tax Act do offer some prospect of deducting travelling expenses necessarily incurred in connexion with the

[1] Jour. of Physiol., 1925, lx., 25; see THE LANCET, 1926, i., 920, and ii., 215.

[2] Journal of Physiology, Feb. 10th, 1923.

lding of an office and employment; but their olication has not been very liberally interpreted. has been held that the expenses incurred by a rgyman in travelling from one curacy to another re inadmissible as a deduction, but that he might luct the cost of visiting his congregation and ending meetings. It was long ago decided that a npany director could make no deduction for the ense of travelling from his residence to his office. was also decided that a solicitor living at Worcester, o happened also to be clerk to the justices at an oining town to which he therefore had frequently travel, could not deduct the expenses of such travel. d, more recently, it was held that a London barrister o was Recorder of Winchester and therefore might e to travel to the latter place four times a year and stay at a hotel overnight on each occasion, could deduct his railway and hotel expenses. The idea s apparently that there was no reason why he should live in Winchester permanently instead of in ndon, in spite of the notorious fact that barristers he experience and standing to justify their selection recorderships do in fact practise their calling in ndon and must live there. A committee of experts ttempting the almost impossible feat of re-drafting income-tax laws in simple language. If so it may noped that the position of travelling expenses may made universally plain. The tax-payer at present riven more and more into the necessity of taking ert advice, and he wonders whether the same ndards of relief or otherwise are applied as between district and another.

STIMULUS IN ECONOMIC LIFE.

THE interrelationship of the sciences has reached n a degree of intensity to-day that it behoves stigators in each field to pause from time to time xamine their categories in order to judge to what nt they have been borrowing concepts which not, in our present state of knowledge, allow for a ersal application. In the mathematical sciences concepts used appear to be of such absolute dity within a given universe of discourse that to stion their validity would merely result in the tion of new concepts to regroup the same facts. epting, for example, the Euclidean notion of ce, or the Kantian intuitions of Space and Time, can arrange phenomena so systematically that ntific prophecy becomes possible over a very wide ge. When, however, discrepancies are discovered he confirmity of phenomena to accepted laws, a orientation is necessary. This we see in the tivistic modification of Newton's laws. In ology, or, more broadly, in the biological study of organism as a system of responses to environtal conditions, the concept of stimulus-response been of inestimable value in describing processes even of numerically relating them, as in Weber's Fechner's Laws. In his Rede Lecture, delivered year and now reprinted,[1] Sir Josiah Stamp wed how the term Stimulus has been repeatedly ked to explain phenomena in the social sciences—icularly in economics. Realising the difficulty of ying so simple and abstract a concept as Stimulus his particular study, the author distinguishes it n incentive and enlargement of scope, and tends efine Stimulus as the increment in incentive which t be distinguished from a mere "shake," which s the opportunity or the occasion for the "realisaof a scope that is already existent." Furthermore, dds that we must distinguish those stimuli which ly act as "detonators or catalysts" from such emical stimuli" as fertilisers which, actually, 'real additions to the other agents." Sir Josiah ores all the avenues of approach, such as types of ulus in economics, which give full permanent s, and those which result in partial gains, status returns and full or permanent losses. He exposes fallacies in the application of the terms to drugs, fertilisers, metal stresses, and economic psychology. In studying his lecture, however, the psychologist may feel a regret that the subject of stimulus and response has not been dealt with from the point of view of dynamic and structure psychology. At the social level of psychology it is surely the whole-felt situation which is met by a highly systematised and dynamic set of purposes or interests (which we call the organism that must be considered, and not the hypothetical units out of which the systems are made. It is doubtful whether in our present state of knowledge it is possible to construct for social phenomena a calculus of increments to explain economic response. Jevons attempted this in his calculus of pleasure and pain. Marshall introduced mathematical graphic methods in his Principles. Recent French work on chronaxie has led to the discovery that within the nervous system Weber's law of psychophysical parallelism holds true. But, with the myriad affective disturbances which qualify group and individual activities, over-simplification and analysis may erect an imposing scaffold which hides the edifice.

AN AMERICAN MEDICAL STUDENT IN 1790.

THE hardships attendant upon practice in country districts has often been a theme for letters and articles appearing in the medical press. Those hardships are real, but the diary of Dr. Eaton, dealing with the conditions existing in New England 130 years ago, makes some of them look very slight.[1] The absence of means of communication, the lack of the necessaries of life, and the primitive methods of practice disclosed in the diary are, of course, long since gone, but it is well to have brought to our knowledge the hard conditions of those far-off days.

The young Thomas Eaton first "talked with his father about going to study physick next summer" on Dec. 2nd, 1791, and was advised to "go by all means." On Jan. 16th, when he was "teaching school, Dr. Butler made me an offer that if I would come and study physick with him, he would take me for 100 dollars (and keep my horse) the whole time for two years, and then if I had a mind to go and ride with Dr. Hassleton a few months he would find me or settle with the doctor. I concluded to give him an answer sometime in the Spring." On March 1st we read that he concluded a bargain with "Doctr. Butler: viz., That I shall live with him two years and as much longer as I please, except I have a mind to spend a few months with Doctr. Hassleton at the last of my time, and if so he is to find me there and my horse at his own cost. He is to board me and my horse and do my washing, &c., and is to have the privelege to ride my horse half enough to pay for the keeping. The first year he is to find all necessary books (except I have a mind to carry a dictionary or two) and am to pay him 30 pounds in cash or stock at cash price, but on the account of his other apprentices it is to be called 40 pounds besides pay for my horse's keeping and if I have a mind to come away any time I have my liberty with paying for the time I am there in proportion to 30 pounds for two years." On the 6th he "sent my snuff-coloured coat, 3 waistcoats, 3 shirts, 2 handkerchiefs, 1 pair of breeches, 2 pairs of stockings, by Doctr. Butler's orders to his house," and must soon have followed his wardrobe for on April 18th he "read 136 pages in Chesleton's Anatomy and got through the second time," only to begin for the third time on the following day. He finished it for the fourth time on May 13th, but never seems to have mastered the spelling of the great surgeon's name, of which he gives another variant later. Anatomy seems to have come no more easily in the eighteenth century than it does to-day! Sunday the 22nd marked his baptism as a surgical dresser, for he "Bled John Marshall, he being the first person that ever I bled." By the 24th

[1] Medical Practice in New England in 1792. Being extracts from the diary of Dr. Thomas Eaton, 1789–1798, and published in the Boston Medical and Surgical Journal for March, 1927, by George Van Ness Dearborn, M.D., Ph.D.

he was a clinical clerk, for he "gathered some snake root." He was no unworthy follower of the great experimenters, for we read that he both bled himself and put a seton into his own leg. The casualty officer will note with a fellow feeling the entry for July 17th: "Pulled a tooth for Joseph Eaton; broke one for John Marshall." By September he had left anatomy behind h m and was "getting through" Sydenham and Boerhaave, Freind's "Emmenologia," Husham "On Fever," and Richard Brookes's "Practice."

An interesting part of the diary is the account given by Dr. Eaton of his visit to the "Pest House" in the following March for the purpose of being inoculated with small-pox. Preparations began on the 21st, when he "swapt stockings with the doctor. Got a pair of linen ones to have to wear to have the small-pox." On the 26th he "rode to the Dr. Jefferies's pest-house in Orange. Inoculated, by his son, Gideon, with the point of the lancet infested, and pierced my wrist very slightly, so that it could not be seen for two or three days after. Agreed to give him 2 pounds for inoculating me and carrying me through the small-pox and he find me in everything." The doctor "would not allow us to eat anything salt, greasy, or sour, but ordered our diet to be skim milk, hasty pudding, and milk porridge. Physic every other morning for three or four days with jalap, &c., and antimony or the essence of antimony so as to work a few times up and down, especially if the stomach be foul; then no more physick at all after the eighth day from the inoculation." Two brief but moving entries record: "Friday, 29th: Took physick. It worked up and down a number of times on each of our company. Sunday, 31st: Took physick again; operated as before." On April 6th his "symptoms held tight. I kept stirring as brisk as possible and feel miserable. My head felt very large and sore and in pain all over. Lost my appetite. I stood it till about sunset, then grew sick at my stomach and a violent pain in my left side. Concluded to bleed myself and go to bed, which eased my pain." That one of the party of five succumbed to the disease given seems not to be a matter calling for much comment by Dr. Eaton, for he merely mentions the fact that he took the disease in a serious form and died; "and a bright young man was he, by name Tristam Coffin, of Epping." All through the year the diary records an alternation of reading—"Chessleton" again in July, Cullen's Nosology and Practice, David Spence's Midwifery, and Samuel Sharp's Surgery—with riding out to bleed, insert setons and prescribe various mixtures and drugs. In July he left Dr. Butler and worked with Dr. Grosvenor. On Oct. 7th he had an attack of influenza "which began with a pain in the breast." The extracts conclude with the proper "happy ending" in 1797, when on Nov. 2nd he "made a request to the parents of Betsy for her to become my wife." On Jan. 3rd they "concluded to be published" and on the 6th "ordered Mr. Greeley to publish me to-morrow." Not even the excitements of a wedding day could abate the young Thomas's ardour for accounts: "Married by Reverend Moses Bradford, for which I reward him with 2 dollars." Gowned in a pink satin pelisse, the 16-year-old Betsy Eaton rode home with her husband on a white horse, and they lived happily ever after.

A MEDICAL MILLENNIUM.

Mr. J. G. Legge is anxious to save the English people from its medical friends, and his amusing book [1] on bureaucracy in public health will be read with interest by those who believe, as he does, that the attempt is still worth making. The scene of his story is laid in England in the period immediately following the war, when everyone was trying to build a New Jerusalem or at the very least Homes for Heroes—the so-called Period of Reconstruction. It opens with the launching of a Ministry of Hygiene which has three main planks in its platform—a housing scheme plan for improving the weather by bringing artific sunlight to the masses, and a proposal to enfo health on the population by such measures as co pulsory periodical examinations, compulsory notifi tion of all diseases, and the establishment of a sanit police force and courts of hygiene. The execution this policy involves a good deal of wire-pulling a intrigue, and these, together with the measures tal to influence public opinion, are described with a de that suggests inside knowledge of political l Parliamentary opposition to the clause of the which establishes the sanitary police and machin for registration eventually prove so great that Prime Minister (who makes dramatic appearances England in the intervals of attending conferences foreign spas) decides not to enforce the meas throughout the country, but to allow local authori to adopt it if they wish. The rest of the book d with the scheme's application at "Rushington," progressive town in the North Midlands, under leadership of its enthusiastic but rather ingenu medical officer of health, Dr. Jollop. At first inhabitants of Rushington rather enjoyed being t by charming young ladies in sky-blue uniforms, exchange their unhygienic headgear for the r sanitary hat, but when they found that the laws to be taken seriously, when doctors were fined sleeping with their windows shut and aldermen w forcibly dieted for their corpulence, there was no of a row. Finally, after the intervention of a climb and treacherous ex-member of the city council financial screw was applied by the Ministry of Hygi itself and the scheme was withdrawn. The m of this book is contained in the quotation fr "Erewhon" placed at the beginning. "Happ common sense, though she is by nature the gent creature living, when she feels the knife at her thr is apt to develop unexpected powers of resistance, to send doctrinaires flying, even when they have bo her down and think they have her at their mercy.

[1] The Millennium. By J. G. Legge. Oxford: Basil Blackwell. Pp. 164. 5s.

LIVER EXTRACT IN PERNICIOUS ANÆMIA

WE published last week a preliminary report the Medical Research Council upon the use of li extract in the treatment of pernicious anæ Numerous requests having been received by Council for particulars of the method of prepa the extract, it has been thought desirable to pub the details of the process by which the material prepared for the trial organised by the Cou The method is as follows:—

To 100 kg. minced fresh ox-liver add 132 litres of 80 cent. alcohol and 109 c.c. of 50 per cent. (vol.) H_2SO_4. frequently and filter after 12–18 hours. Suspend the ti again in 250 litres of 50 per cent. alcohol, stir frequently filter after 12–18 hours. Evaporate the combined filtr *in vacuo* to a volume of about 10 litres. Add 10 litre absolute alcohol. A flocculent precipitate is formed w settles. The supernatant fluid is removed and the resi is centrifuged and washed with 50 per cent. alcohol. alcoholic liquid and washings are combined, evapor *in vacuo* to as small a volume as possible and then pou with constant stirring, into ten volumes of absolute alco The syrupy liquid is slowly dehydrated by the alcohol assumes a toffee-like consistency. This material is pu into long shreds to expose fresh surfaces to the dehydra action of the alcohol. When the dehydrating action of alcohol is exhausted it is replaced by fresh alcohol and material is broken up and eventually becomes brittle. is then filtered off and dried (*in vacuo* over H_2SO_4, or other suitable means). It is then powdered rapidly again dried as before. The material must be exposed the air during these operations as little as possible, as very hygroscopic. The dry powder is transferred to tu each of which should contain an amount equivalent 250 g. of the original fresh liver.

It is to be noted that the method here describe based upon the American process of which an acco has been published by Cohn and his co-work As was stated in the Council's report, this particu modification has not necessarily any peculiar va as compared either with the original process or w

ossible alternatives, but the experiments made for ie Council have shown that it is one which is capable f ready application on a large scale, and which, ccording to the clinical indications, yields a satis- ctory product.

THE GROWTH OF POPULATIONS.

THOUGH it is difficult to wrench the mind to a full ealisation of the implications of the prospect, there eems to be very little doubt that the population of his country will become stationary in another 20 ears or so unless some revolutionary change in our elation to our environment intervenes. Experts who udy the question all come to the same conclusion. rof. A. L. Bowley takes the facts of death-rates and irth-rates in relation to the age-distribution of the opulation as they stand, and predicts the rapid attain- ient of a population in which births and deaths will just bout balance one another. Prof. Raymond Pearl aches the same conclusion on broader biological lines, id publishes in the last number of his *Quarterly Review Biology* [1] a revised version of a paper [2] which he ad at the World Population Congress at Geneva st year when, as some of our readers may remember, e also lectured on the subject in London. He finds at populations of all kinds—bacteria, yeast, the y *Drosophila*, and man—follow the same curve of owth, increasing slowly at first, then faster and ster (as we did in the first two-thirds of the nine- enth century), and then gradually slowing off until ie rate of increase becomes imperceptible. His iagrams certainly show a remarkable similarity which akes it easy to believe that the same explanation ust underlie the whole of them. He points out at this uniform type of curve is derived from eath-rates and birth-rates if it is postulated (1) that rth-rates are much diminished by small increases density of population when the density is thin, and latively little afterwards when the density becomes eater; and (2) that death-rates are not much creased by increasing density of population until ie density becomes considerable. Experiments with rosophila show these relations between births, eaths, and density, which between them account dequately for the facts observed in the growth of xperimental populations, and the similarity of the ain phenomena with those observed in man makes at least possible that the same factors are important r human populations too. "High" and "low" ensities of population cannot, of course, be defined umerically; they differ very widely in different ecies and, in the same species, depend on the vironment. Like other animals, man adjusts his ensity to his surroundings and tends to have the rgest population which is compatible with the mfort and convenience which he judges to be the ecessary minimum; the abundance of a plant opulation depends chiefly on the room available, of ats on the food-supply, and of man on the same and milar considerations; the density in 1900 in this untry would have been impossible overcrowding 1600. The prospect of a stationary population cause for neither glee nor apprehension; if man is llowing a general biological law, it is inevitable and resumably good for him.

CAROTINÆMIA.

IN a recent paper on this subject Dr. Willard C. toner,[3] of St. Luke's Hospital, Cleveland, who escribes a case of his own, remarks that after the ar German authors described under the name of arotinæmia a number of cases with a peculiar iscoloration of the skin which was obviously due the high vegetable diet of the population.[4] The condition was most often seen in children who had been having exclusively vegetable diets rich in carrots and greens. The chief interest of the condition, which is unaccompanied by any symptom of constitutional disturbance, lies in the fact that it may be confused with true jaundice, the principal difference being the absence of pigmentation of the sclerotics of patients with carotinæmia. The cutaneous discoloration is due to "lipochromes" which are found in substances such as milk fat, yolk of egg, body fat, and certain vegetables such as carrots, green vegetables, and oranges. Their excretion sometimes alters the colour of the urine. Dr. Stoner's case is unusual in that it occurred in an adult, a woman aged 65, who had been living almost exclusively on a diet of vegetables, including carrots, for several months. The skin showed a slight generalised yellowish pigmentation, which was most intense on the palms and soles. There was no pruritus—a symptom which is usual in jaundice—and the sclerotics were not discoloured. The temperature was normal, and apart from flatulence and constipation, which had been present for years, no other symptoms were noted. Examination of the urine was negative, but appropriate tests showed carotin in the blood. What finally happened to the patient is not reported, but presumably, as in other cases on record, the discoloration of the skin disappeared when the diet was changed.

WHAT IS CELL RESEARCH?

UNDER this title our Budapest Correspondent sends an account (p. 572) of a lecture by Prof. Michael Lenhossék, in which attention is again drawn to the revival of interest in normal and pathological histology. For those who could see a little deeper than the crest of the wave, these subjects never have been dead, they must always be the basis of our knowledge of the structure of the normal and the abnormal. But the study of histology is tedious and difficult; results demand great industry, and are much more easy to obtain in other fields. Though accepting the dictum that function is dependent on structure, both physiologists and pathologists have tended to explore other paths in their search for the truth. It is, and has been, very necessary that they should do so, but it is a matter for general congratulation that interest has become focused once more on what are, after all, basic studies. This happy result is entirely due to the adoption of the experimental method. By vital staining methods, and by micro-dissection and manipulation, it has become possible to learn more about the structure and behaviour of the living cell than could be hoped for by the study of fixed and stained material alone. Probably the most important technique of all is that of tissue culture. The possibility, first shown by Ross Harrison some 20 years ago, of growing cells outside the body, just as bacteria are grown, has opened up lines of investigation of great promise. For the most part this method has been used by pathologists, and for the investigation of cancer. But it should have a much wider field. The substitution of artificial media for the fluids of the body has made the technique of tissue culture easier than it was, but it is still much too difficult for universal application. If and when it becomes simplified it should be feasible to study the growth and structure of the living cell in a way which is at present impossible; and by using the growing cells as indicators of the nature of the medium on which they are growing, to investigate those problems of metabolism and environment which now elude us. It would be unwise, however, to draw inferences too readily from the behaviour of cells in vitro, for the cells of the tissue culture approximate closely to unicellular organisms, and it would be just as fallacious to seek the answer to the questions of human physiology from the behaviour of the amœba as to expect the tissue culture to be entirely representative of the body tissues. While welcoming these new means of

investigation, it should not be forgotten that the experimental method can be applied with benefit to the older techniques—and inasmuch as the whole basis of the experimental method is adequate control, the workers in the more dynamic forms of histology must always be prepared to check their results by resort to the older techniques.

THE DISCOVERY OF ETHER ANÆSTHESIA.

THE granting of official rewards for scientific discoveries is always attended with the difficulty of distinguishing between the claims of rival discoverers, for the ground may be prepared by unrecognised workers, and the actual reaping is inevitable. The recognition of the truth may be delayed perhaps, but sooner or later it must be perceived, and it is hard to say whether he who enunciates it is more worthy of recognition than those who made his discovery possible. There seems to be no doubt that Crawford W. Long performed on March 30th, 1842, the first operation to be carried out under ether anæsthesia, and it is exceedingly interesting to learn how this came about.[1] It appears that in the first half of the nineteenth century certain individuals used to travel about England and the United States lecturing on chemistry. During these lectures it was the custom to invite members of the audience on to the stage to inhale laughing gas and ether vapour for the purpose of causing exhilaration and mirth-provoking antics. The inhalation of ether to produce excitement and exhilaration became quite popular. Dr. Long introduced it to his circle, and it is amazing to us to read that he and his friends used to indulge in "ether frolics." Long noticed that he and others sustained bruises and minor injuries while under the influence of ether without any consciousness of pain, and it occurred to him that he had at his command a means of obviating the terror of a surgical operation. And so from what we should regard as a highly reprehensible practice came the wonderful discovery of ether anæsthesia. Mrs. Frances Long Taylor, with the intent to establish her father's claim to be the discoverer of ether anæsthesia, has drawn the picture of a fine and distinguished man.

THE Lumleian lectures will be delivered at the Royal College of Physicians of London, Pall Mall East, S.W., on March 22nd, 27th, and 29th, at 5 P.M., by Dr. James Collier. His subject will be Epilepsy, and members of the medical profession will be admitted on presentation of a visiting-card.

EASTER TUBERCULOSIS CONFERENCE.—A provincial meeting of the Tuberculosis Society and of the Society of Superintendents of Tuberculosis Institutions will be held at Oxford from March 29th to 31st, and the Conference will deal in successive sessions with four subjects—Lupus and its Treatment; speakers, Sir StClair Thomson, Dr. W. J. O'Donovan. The Potentially Tuberculous Child; speakers, Dr. A. L. Ormerod, Dr. G. Macdonald, Dr. Esther Carling. Treatment of Hæmoptysis in Pulmonary Tuberculosis; speaker, Dr. Clive Riviere. Intestinal Tuberculosis; speakers, Prof. M. J. Stewart, Mr. L. E. Barrington-Ward, Dr. Marcus Paterson. The Chairmen at successive sessions will be Sir Farquhar Buzzard, Sir StClair Thomson, Prof. Lyle Cummins, Dr. F. R. Walters. The meetings will be held in the pathological lecture theatre at the Dunn Laboratory. The annual meetings of both Societies will take place at the Clarendon Hotel on the evening of the 29th, and on the following evening there will be a dinner to entertain visitors. Accommodation can be arranged at the Clarendon Hotel, for any who wish to avail themselves of it, on application to Dr. G. T. Hebert, Tuberculosis Department, St. Thomas's Hospital, London, S.E. 1.

Modern Technique in Treatmen

CCLXVII.

THE TREATMENT OF HEAD INJURIES.

I. GENERAL MANAGEMENT.*

THE treatment of head injuries causes more anxie than almost any other emergency of practice, and the early stages prognosis is quite uncertain. Ea case differs from the last in the manner of its evolutio and successful management depends on close a continuous observation of the signs during the peri of danger, and on a clear understanding of the ma pathological processes that may be set in train.

Emergency Treatment.

We are called, let us say, to treat a head inju shortly after the accident has occurred. The unco scious patient has been removed to the nearest shelt A hasty examination is made to answer the followi questions: (1) Is the patient collapsed? (2) Is the bleeding from the scalp? (3) Are there any fractur of the limbs? At this stage the patient is interfer with as little as possible, and if he shows signs collapse it may be necessary to delay his removal hospital for an hour or so, until his pulse has rallie Stimulants are to be avoided; the state of concussi is one which tends towards spontaneous recovery, a any artificial stimulation of the blood pressure is like to increase the risk of subsequent intracrani hæmorrhage. Cases which at this stage are showi signs of increasing collapse are inevitably fatal.

The patient is kept warm and is placed in such position that his breathing is free. Bleeding from lacerated scalp can be easily controlled by digit compression of the scalp against the intact part of t skull on each side of the laceration, if necessary considerable distance from the wound itself. This a matter which can be delegated to lay assistants aft slight tuition. Tourniquets for the scalp are le satisfactory than pressure by the fingers, for they a apt to slip.

It is of great importance that the patient should removed to a hospital or nursing home rather tha to his own house. It is impossible to foretell at th stage whether an operation will later be require Moreover, in hospital it is more easy to make t systematic observations that are necessary for t successful management of each case, and to enfor the prolonged rest in bed on which complete a permanent recovery so often depends.

Systematic Observations.

Apart from the care of open wounds of the hea which will be considered later, the treatment of patient who is suffering from a recent head injury at first essentially conservative. He is placed in warm bed in a room free from noise, and the followi observations are made:—

(1) The state of consciousness. If the patient is unco scious the depth of coma should be investigated by notin the pupillary and corneal reflexes, the response to pin-pric the flaccidity of the limbs and so forth.

(2) The state of the pulse, temperature, respiration, a blood pressure.

(3) The size and reaction of the pupils.

(4) The sensation and, if possible, the movements of t limbs and face.

These observations should be made every hour, a the facts noted should be committed to paper at t time.

It is well to remember that an unconscious patie bearing the marks of a head injury is not necessari suffering from the effects of head injury. In hospit practice, especially, a number of other conditio frequently masquerade as head injury—notab

* A second part will be published next week.

rebral hæmorrhage, ruptured cerebral aneurysm, rebral thrombosis, and acute alcoholism. Moreover, e irritability of a patient with severe traumatic tracranial hæmorrhage may closely simulate that of ute alcoholism. For the differentiation of these nditions lumbar puncture is of definite value. Blood rarely absent from the cerebro-spinal fluid in severe tracranial trauma.

Though fractures of the skull are often absent and ways relatively unimportant in head injuries, and ough their discovery may even be confusing if it is t borne in mind that the greatest damage of the ain is apt to be, as a result of contre coup, on the posite side of the head, it is nevertheless advisable at skiagrams of the skull should be taken. casionally they give information which is of immeate value, but their chief importance is medico-legal. ray examination is best made as soon as the tient is admitted to hospital and before he is put bed, as undue movement is in this way avoided.

The Classification of Cases.

During the period of observation it is necessary to ake some estimate of the type of case being dealt th, in order that a rational line of treatment may be rsued. It will be found that each case can be signed to one or other of the following groups.

(*a*) *Fatal Cases.*—In some cases deep coma is aintained from the moment of injury; while the spiration grows more stertorous, the pupils become lated and inactive, and the blood pressure and mperature mount rapidly. These signs indicate a eatly raised intracranial pressure, due to damage of e vital centres that we are powerless to repair. ch cases are invariably fatal. Operation, it should emphasised, is of no avail in this type of case.

(*b*) *Mild Cases.*—In other cases it soon becomes ident that recovery is taking place. The initial consciousness is of short duration and is followed a stage of reaction, in which the patient is apt to extremely irritable and liable to sudden attacks of miting. There is severe headache. These are cases mild concussion and contusion, and they are treated nservatively by methods to be described later.

(*c*) *Doubtful Cases.*—There is another group of ses in which the issue remains for some time in ubt. For a day or more the patient remains uncon-ous, or shows periods of semi-consciousness alterting with periods of actual coma. These are cases severe contusion and laceration of the brain with condary œdema. There is a moderately severe and stained rise of intracranial pressure. Treatment is ried out on conservative lines, unless there are rsistent focal signs to indicate an area of local ntusion for which operative decompression will be value.

Other doubtful cases are those which show what is own as the "lucid interval." The patient recovers rtially or completely from the unconsciousness of ncussion, but, after a lucid interval of variable ration, lapses once more into coma. In this tegory also are those cases in which the patient is ly dazed at the moment of injury and is able to lk up to hospital, but then becomes unconscious. e lucid interval is an indication that the compression, rise of intracranial pressure, which produces the ondary state of unconsciousness, is due to gradually cumulating intracranial hæmorrhage, such as morrhage from the middle meningeal artery, or to a dually developing cerebral œdema, rather than to ual damage to the brain at the time of the injury. is not always easy to know, after a patient has overed from the initial unconsciousness of concusn, whether he is merely drowsy or whether he is ssing into the coma of compression. Here we are ided by our systematic observations; the onset of mpression is associated with slowing of the pulse, e of temperature, and, most important of all, with rise of blood pressure.

Those which show the lucid interval call for operan more than any other cases of head injury, with e exception of those in which there are compound fractures of the vault of the skull. Conservative treatment may be tried for a short time if the rise of intracranial pressure is not rapid, but should be immediately abandoned for operative treatment if it meets with no success.

Prevention of Infection.

While an attempt is being made to ascertain the extent of injury to the brain the spread of infection to the brain through open wounds must be prevented. Compound fractures of the vault of the skull call for immediate operative treatment, in a manner to be described. A leakage of blood or cerebro-spinal fluid from the nose or ears is presumptive evidence of an open wound through fracture of the base of the skull. In such cases also there is risk of meningitis. The external ear should be gently swabbed out—*never syringed*—with a mild antiseptic, such as perchloride of mercury 1/1000, and the auditory canal should be lightly plugged with a pledget of gauze, soaked in similar solution, which is changed every hour. For a leak of blood and cerebro-spinal fluid through the nose all that can be done is to keep the anterior nares free from clot. Urotropine, grs. x. t.d.s., should be given by mouth whenever meningitis is feared.

HUGH CAIRNS, M.B., B.S. Adel., F.R.C.S. Eng.,
Assistant Surgeon to the London Hospital.

NATIONAL HEALTH INSURANCE.

A BILL TO SUPPLEMENT THE ACTS OF 1924 AND 1926.

THE National Health Insurance Bill just presented to Parliament is of interest to the medical profession for its omissions rather than for what it contains. The official memorandum, explanatory of the Bill, which has been issued as a Command paper,[1] states that the Bill—containing 22 clauses and two schedules of some length—is based mainly on the Majority Report of the Royal Commission. It will be found on examination of the contents of the Bill that this does not mean that the Bill gives effect to the main recommendations of the Commission, at least so far as the medical service for the insured is concerned.

Its Scope and Limitations.

It has already been stated in Parliament that the Government do not propose to accept the recommendations of the Royal Commission as to the abolition of insurance committees or as to the partial pooling of the surpluses of approved societies. The Bill accordingly contains nothing on these subjects. The fresh lease of life for insurance committees is of interest as a further illustration of the vigour of those bodies whose existence is threatened from time to time. The absence of any provision for the partial pooling of the surpluses of approved societies is disappointing for those who had hoped for a much-needed improvement of the medical service for the insured. For it was by such means that the proposed extensions of this service were, in the view of the Royal Commission, to be financed. It may be recalled by those who studied the report of that body early in 1926[2] that the Commission placed their recommendations in regard to extensions and improvements in the insurance service in order of priority, and gave first place to the widening of the scope of medical benefit so as to include the provision of (*a*) expert medical advice and treatment for persons who can travel to meet the specialist; (*b*) expert advice for persons who are unable to travel; and (*c*) laboratory services. We stated at the time that—

this recommendation has very properly been given priority as the medical benefit under the Act has suffered throughout

[1] Cmd. 3051. H.M. Stationery Office. 3*d*.
[2] See THE LANCET, 1926, i., 501, 515, and 676.

from limitations imposed by financial considerations, and stated by the Commission to call urgently for removal. It would seem that, owing to the fact that sickness has cost less than was originally anticipated, there is a margin available out of the present contributions, and the Commission expressly recommends that this margin should be applied to its full extent towards meeting the cost of extending the statutory benefits. The medical profession, as made clear by their evidence, are ready to coöperate with the Government in bringing into operation the extension of the scope of medical benefit which is contemplated.

The greater part of the "margin" was shortly afterwards employed to bring about a reduction in the Exchequer contribution towards the cost of benefits generally, and the proposal that remained—that one-half of the future surpluses of approved societies should be used to find the money for a general extension of the medical service, estimated to cost a million and a half pounds per annum—now finds no place in the Bill which is based on the Commission's report.

Inequalities of Benefit.

With regard to the value of the medical service for the insured, the Commission reported that the general acceptance of the system during the 13 years since its introduction, the absence of any substantial volume of criticism of it apart from the question of scope already referred to, and the wide demand for its extension, were in themselves evidence of a favourable kind.

We must suppose that there are grounds, financial or otherwise, which commend themselves to the Minister of Health as adequate for the failure to give effect to any recommendation of the Royal Commission for extension of benefit, not even that placed first in order of priority. The system therefore continues by which those societies having surpluses apply the whole available surplus (that is, that part of the surplus declared on the quinquennial valuation to be available for the purpose) to certain statutory "additional benefits." It is worth recalling what the Commission had to say in regard to the resultant inequalities of benefit.

> We received much evidence in criticism of the inequalities of benefit which result from the variations between the valuation surpluses of approved societies and of the confusion alleged to be consequent on the comparative freedom which societies enjoy in selecting and, indeed, in defining the content of additional benefits other than the increase in the rates of the cash benefits. . . . Other witnesses contended vigorously for the maintenance of the present system. . . . Some of those who advanced this claim relied on pledges given when the Bill of 1911 was before Parliament, to the effect that, to meet this difficulty, insured persons should be free to choose their own societies and the societies should have full control of their own surpluses. In this particular sphere, indeed, it became evident that we had to recognise the existence of opposed and apparently irreconcilable opinions held in each case by schools of thought whose views were entitled to respect and consideration.

List of Additional Benefits.

The complete list of "additional benefits" appears in the new Bill in substitution of existing lists, and is as follows:—

1. An increase of sickness benefit and disablement benefit.
2. The payment of sickness benefit from the first day of incapacity.
3. An increase of maternity benefit.
4. Allowances to a member during convalescence from some disease or disablement.
5. Payments to or on behalf of members who are in want or distress.
6. Payments to members not allowed to attend work on account of infection.
7. Repayment of the whole or any part of contributions payable under this Act by members of the society or any class thereof.
8. The payment of the whole or any part of the cost of the provision of dental treatment.
11. The provision of premises suitable for convalescent homes and the maintenance of such homes.

* * *

9. Payments to hospitals in respect of the maintenance and treatment therein of members, and the payment of the whole or any part of the travelling expenses incurred by in respect of members in travelling to and from hospitals
10. The payment of the whole or any part of the c of maintenance and treatment of members in convalesc homes, and the payment of the whole or any part of t travelling expenses incurred by or in respect of memb in travelling to and from convalescent homes.
12. The payment of the whole or any part of the cost medical and surgical appliances, other than dental a optical appliances and those provided as part of medi benefit.
13. The payment of the whole or any part of the c of the provision of ophthalmic treatment (other than provided as part of medical benefit) and the whole or a part of the cost of optical appliances.
14. The payment of the whole or any part of the c of the provision of nurses for members.
15. Payments to approved charitable institutions respect of any treatment of members required for the p vention or cure of disease, not being treatment within t scope of any other additional benefit or of medical benefit.
16. Such other additional benefits, being of a charac similar to that of any of those hereinbefore mention as may be prescribed.

New and Old Benefits.

This list is of interest to doctors, who are frequent asked by their patients about these addition benefits. They can merely refer the inquirers to the respective societies who, where there is an availab surplus, may provide one or more of these benefit All that the doctor can say with reasonable certain is that any form of benefit not in the list cannot obtained under the Insurance Acts. For instanc the proposed extension of medical services to whi we have referred does not appear in the list. It subject to the same objection as that which h now disappeared from the list, but which was alway and would have remained, a "dead letter"—t provision of medical treatment for the dependan of an insured person. In recommending its remov from the list, the Royal Commission said that extension of the scope of medical benefit should n be made in this way (that is, in certain cases and n in others), and that it was in fact impracticable, it would have to be administered by the insuran committee responsible for the administration medical benefit and not by the society having a surpl which it proposed to devote to this purpose. (It w be borne in mind that one society may have membe spread throughout the country in a large number insurance committee areas.) The extension of medic benefit to dependants of insured persons general was out of the question because of its great cost.

In the above list we have transposed item 11 so as show, below the line of asterisks, all those benefi which did not appear in the Act of 1924; some have be prescribed since that date by departmental regulatio others are new. It is important to observe wi regard to these generally that a long-standing que tion, as to whether certain forms of benefit appearin the list are or are not "in the nature of medic benefit," and therefore due to be administered l insurance committees, is settled by including s additional benefits in one class and making it cle that they are administered by approved societie A distinct gain in the control and standard of the various benefits is secured by the provision in th Bill that regulations may be made by the Minist in regard to them. The explanatory memorandu says that these regulations are required in order t secure that the large sums (approximately £4,000,0(a year) now spent by upwards of 7000 societies ar branches on additional benefits in the form of trea ment shall be administered with a proper standar of efficiency and uniformity, and in the best interes of the members.

The memorandum adds that if any of the forms treatment at present covered by additional benefi should at any future time be made generally availab to all insured persons as statutory benefits the administration would be transferred to the insuran committees on lines similar to those at prese governing the administration of medical benefit.

Other Provisions.

Amongst the other provisions of the Bill of general terest to practitioners may be noted—

the fact that all persons on ceasing to be employed are to remain fully insured for all benefits over an average period of one year and nine months (this period commencing, where the unemployment is due to sickness, after the sickness terminates);

a clause which prevents bodies of persons from contracting out of the medical benefit provisions of the Acts by taking advantage of a provision—intended for individuals making their "own arrangements"—to secure, in effect, the recognition of medical institutions which would otherwise be outside the Act;

a more careful regulation of the right of societies to subscribe to a "charitable institution" and a definition of such an institution which makes it clear that it must have a real and substantial charitable element and not be merely a body financed by approved societies and designed to give treatment beyond the control of the Minister of Health; and

a minor provision by which medical benefit includes, in addition to provision of medicines, such chemical reagents as may be prescribed; this will, for example, give the department the opportunity of regularising the use of Fehling's solution (which has been held to be not a "medicine") in connexion with the administration of insulin.

IODERN RADIOLOGICAL EQUIPMENT.

THE NEW DEPARTMENT AT EDINBURGH.

THE new Radiological Department at the Royal firmary, Edinburgh, is an outstanding sign of the portant position which radiology has reached at e present day. In the past, the visitor to an known hospital, desirous of finding the X ray partment, had only to descend to the cellars, in the rkest and most noisome corner of which the depart-ent would certainly be found. The idea that any ace is good enough for the radiologist is slowly ssing away, and in the future the X ray department an up-to-date hospital will be planned and built om the very beginning with a view to fitness for special work, as in the case of the Edinburgh partment.

General Arrangement.

The building, which was opened on Oct. 9th, 26, by the Duke of York, is 170 feet long, with an erage width of 60 feet. It consists of a basement d two floors, with a flat roof. It is built along the stern side of the curved passage between the rgical and medical blocks, known to all Edinburgh edicals as the "duodenum." The building is of el-framed construction with reinforced concrete ors and roof, and with walls of Craigmillar stone. is consequently fire- and sound-proof. One of the ost important factors in the design of rooms in which radiations of high penetration are to be generated the provision of adequate protection of the operators d the prevention of the escape of radiations which ight in time affect workers in adjacent rooms. In e past this second end has been achieved by lining e walls and doors with heavy sheet lead, but in a ilding of such size as this the cost would have en prohibitive. It was therefore decided to incor-rate the protection in the building material used r the construction of the walls. Concrete slabs of e following composition were used: rough sand, part; engine ashes, 2 parts; Portland cement, part; barium sulphate, 3 parts. The slabs were ngued and grooved, and when built the walls were ated on each side with a layer of barium plaster inch thick. The walls and ceilings were also coated ith this plaster. All screening, radiographic, and eatment rooms were thus protected. The National Physical Laboratory reported that the finished walls gave protection equivalent to 5 mm. thickness of metallic lead, when a peak voltage of 100 k.v. was applied to the tube. The doors are protected with 6 lb. lead on both sides. The radiographic and screening rooms are provided with protected cubicles, built with the same barium slabs, in which all controls are placed. The meters and patient are observed through windows glazed with two thicknesses of "Super Protex" lead glass, giving protection equal to 5 mm. of lead.

Further points of the greatest importance in the design of a radiological department are the avoidance of the noise of rotating machinery and of corona high-tension discharges, with the consequent pollution of the air of the rooms by ozone and oxides of nitrogen. In the Edinburgh department all rotating machinery has been placed in the basement, in one large machine room with thick rubber flooring.

The Electrical Installation.

Direct current at 460 volts, from the town mains, is brought into this room, and used to drive a motor generator of 42 k.w. capacity, which supplies alternating current at 200 v. 50 cycles to the whole department. There is also a 3 k.w. rotary convertor for use with an emergency set. A third 1 k.w. motor generator supplies D.C. at 80 volts for electrical treatment. The switch gear for both D.C. and A.C. sides of the main generator is grouped in the centre of the room, the wiring at the back being completely caged in. To avoid inconstancy of radiographic results, due to voltage changes resulting either from changes of load in the department or from line fluctuations in the town supply, a Tirrill automatic voltage regulator is used to control the output of the 42 k.w. motor generator. In practice this instrument is very satisfactory, the 200 volt A.C. supply being always perfectly steady. Three oil-immersed 10 k.v.a. high-tension transformers are installed in the machine room, each being directly under an X ray room on the floor above. The high-tension current is led up to the room above by aluminium tubing passing through glass insulators in the machine room ceiling. Each transformer is capable of an output of 100 m.a. at 150,000 volts (peak), and is controlled from a trolley table in the cubicle in the room above. Each transformer, with its mechanical rectifier and coolidge transformer is enclosed in a metal cage, on the door of which is a red danger sign, which lights up automatically when the main switch in the corresponding room above is closed, thus warning anyone below that the transformer is about to be energised.

These transformer units feed the two screening rooms and the main radiographic room. Next to the machine room is a mechanics' workshop, well equipped with electrically driven machine tools. There is also a very large fireproof room for filing films returned from the wards.

As a result of the grouping of the machinery in the basement there is no perceptible noise or vibration in the X ray rooms. When a screen room is in use, the only sound is a faint hum from the corresponding rectifier below. As all the high-tension wiring is carried out with smooth tubing, sharp bends being avoided, there is no corona in any of the rooms. Ventilation is carried out by a system of air extraction ducts at ceiling level, three high-speed electric extraction fans, for the different sections of the building, being installed in one roof tower, while fresh air inlets are provided at ground level. Practically all the rooms have wash-hand basins with hot and cold water, and all are floored with polished oak. In the corridors the floors and wall dado are of white terrazzo, with light blue decoration.

Radiographic Rooms.

An automatic push-button control passenger lift connects the basement with the floors above. On the first floor is the office at which patients are received, two radiographic rooms, dark rooms, director's room and secretary's room, deep and superficial therapy rooms. There are also a lecture or demonstration room and various staff rooms. The main radiographic room, fed from one of the transformer sets in the basement, contains a Bucky couch, ordinary couch for radiography, and a screening couch for localisation work. As all the controls, including an electro-magnetic remote control for the Bucky

diaphragm, are in the completely protected cubicle, the operator in this room is never exposed to X rays at all, as the tube can only be switched on from inside the cubicle. In the partition wall between the radiographic room and the dark room are two hatches with double lead doors. Through one of these fresh cassettes are obtained, while the exposed ones are passed in through the other. The two screening rooms are similar to each other, one being mainly intended for gastro-intestinal work, and the other for chest cases. Both have three section screening stands.

These consist of a large framework fixed to the floor and carrying the tube box. This, though very heavily protected with lead, can be moved with great ease in both horizontal and vertical planes. The section on which the patient stands, and the third one carrying the operator's seat, both run on rails allowing the patient to be moved away from the tube for tele-radiography. In front of the operator's seat is a counter-weighted, lead-protected, wooden screen with side wings, which normally rises and overlaps the lead glass protection of the fluorescent screen. It can be depressed temporarily to allow of palpation. This arrangement makes the wearing of a lead-rubber apron quite unnecessary. Each room also has a screening couch, with the fullest protection. One screening room has a Selecteur Béclère apparatus for rapid serial radiography of the duodenum, while the other has an apparatus with slot diaphragm and moving film for recording the movements of the heart. Both rooms are rapidly darkened by lowering a steel roller blind by means of gearing, but when not in use they can be thoroughly aired and exposed to daylight. Both have all controls inside the cubicle. All the high-tension wiring is carried out with aluminium tubing, supported by insulators fixed to the ceiling. Connexion to the various units is made by means of overhead H.T. switches, which instantly change over both H.T. and filament currents, without disconnecting any wires by hand. Both wiring and switches are entirely corona-less. Where the H.T. feeders enter the room through the floor, they are enclosed in a metal cage, to a height of 8 ft.

The large lecture room is equipped with viewing boxes, two stereoscopes, and a projection lantern.

Treatment Rooms.

Both deep and superficial therapy rooms open into a large operators' room, in which the workers are entirely protected from radiation by the barium walls and lead doors. The respective switchboards are at the side of lead glass windows through which the patients are watched.

In both rooms the high tension generators are the Gaiffe-Pilon constant current apparatus, which employs high-tension transformers, charging up large condensers through rectifying valves of the hot cathode type. The steady "overflow" from the charged condensers constitutes the high-tension supply to the X ray tubes. An oscillographic record of the current curve of this type of high-tension generator results in an almost straight line, which indicates that the voltage generated is almost constant, there being only a slight ripple. This means that the X ray beam emitted by the tube is practically homogeneous as regards wave-length. Moreover, the life of the tubes is prolonged as their anticathodes are not subjected to the rapid heating and cooling which occurs when a tube is energised by ordinary rectified A.C., and which causes a breaking up of the tungsten at the focal point. The high-voltage generator, which is placed in a safety cage inside the deep therapy room, is capable of an output of 10 m.a. at 250,000 volts. The hot cathode X ray tubes are immersed, for insulation and cooling, in oil which is contained in a metal tank. The oil is cooled by a radiator immersed in it through which cold water circulates. The tank is entirely surrounded by 6 mm. of lead, with the exception of the small aperture through which the X rays are emitted.

Patients may be treated singly, or two can be irradiated simultaneously, in which case the two tubes are used in parallel from the one generator. In this case both tubes have the same applied potential, but the milliampèrage through them is under independent control. A similar, but smaller, constant current generator with an output of 10 m.a. at 125,000 volts, supplies the superficial therapy room. A striking feature of both these high-tension generators is their silence and absolute steadiness when in operation. Once the kilovolt and milliampère meters have been set to the desired reading, they remain there without any fluctuation throughout any length of treatment. Notable characteristics of both therapy rooms are their great height, absence of corona, a excellent ventilation, all factors of the greatest impo ance if sickness after treatment is to be avoided. complete X ray unit, with transformer and combin couch and screening stand, is provided in the em gency room. This transformer can be supplied eit from the main motor generator or from a 3 k. rotary converter which, though situated in the ba ment, is controlled from the emergency room its This allows of the use of the equipment when t main generator is not running. Dental radiograp is also done in this room. The Victor dental set used, with a dental chair with full movements.

The dark rooms are also on this floor, and cons of the radiographic dark room, a second one f print and slide-making, and a large drying room.

Massage and Electrotherapeutic Department.

The first floor is occupied by the electrotherapeu department.

One large room is equipped as a gymnasium for remed exercises. Adjoining the gymnasium are the two la male and female massage rooms. Massage couches placed round the walls of the rooms, and above each cou is a wall type treatment board, fed from the 80 volt mo generator in the basement, from which both faradic a galvanic currents can be obtained. At intervals arou each room are patresses with four non-interchangeal plug sockets, to each of which is led a different suppl 230 volts D.C. from the town mains; 200 volts 50 cyc from the motor generator; 80 volts D.C. from the sm motor generator; and 4 volts D.C. from accumulato Each room also contains a Schnee bath.

There are, in addition, several small treatment roon Three diathermy machines are provided, and a high-frequen apparatus. Three rooms are used for ultra-violet lig therapy. Of these, two have carbon arcs, of which there two in each room. The arcs take 30 ampères, and each p is used in series on 230 volts D.C. The third room has t atmospheric mercury-vapour lamps. A hot and cold show bath is provided for patients.

The radium department, also on this floor, has waiting room, and a treatment room. A special saf with very heavy lead protection, is used for the stora of the radium. The treatment room is provided wi wash-basin, electric steriliser, &c.

There is also a photographic studio, for clinic photography, with a dark room next door.

The building was designed and its constructio supervised from the beginning by Dr. J. M. Woodbu Morison, medical officer in charge of the departmen and Mr. T. W. Turnbull, A.M.I.Struct.E., Master Works, Royal Infirmary, Edinburgh. All the electr wiring and plumbing was carried out by the pe manent staff of the infirmary. The entire X ray a electrotherapeutic equipment was supplied a installed by Messrs. Watson and Sons (Electr Medical), Ltd. The approximate cost of the buildi and its equipment was £52,000.

MEDICINE AND THE LAW

Death after Vaccination.

ON Jan. 24th an inquest was held at Warringt touching the death of J. H. Chetter, a fitter's labour employed by Joseph Crosfield and Sons, Ltd., soa and chemical manufacturers. A few weeks earli there had been a local outbreak of small-pox. Tw cases having occurred at the company's works, t management invited all employees to be vaccinate While vaccination was optional, workmen who refus to be vaccinated were informed that they would suspended from work for an indefinite period. T deceased man, though reluctant to be vaccinate agreed to take this precaution rather than be suspend from his work. He was vaccinated on the 5th wi four injections in his left arm. He continued at wo until the 11th when, owing to the swollen conditi of his arm and the pain he was suffering, he was se home during the morning. On the 13th he visit his panel doctor and obtained a sick note. Thr days later he visited the doctor again and was order

bed. On that day and on the 18th the doctor saw im at his home. His condition grew worse; he could ot open his mouth; tetanus was suspected, and e was removed to the Warrington Infirmary. He ied on Jan. 20th, and, as the infirmary doctors were nable to assign a definite cause of death and con- dered that the vaccination might have been a con- ibutory cause, Dr. E. E. Bowden, police surgeon, ıade a post-mortem examination and an inquest was eld. The employers and relatives were informed ıat they could be professionally represented at the ost-mortem examination, and Dr. Bowden's deposi- on stated that about 15 medical practitioners were resent. His deposition concluded as follows: "It hard to say that the vaccination accelerated death; e was not healthy; he was fatty." Dr. Bowden's ost-mortem examination report was to the effect ıat externally the body was well nourished with a rge amount of fat; the right leg showed scars of ealed ulcers; on the left arm the vaccine scars ppeared to be quite normal for the period (15 days) nce vaccination; internally the organs of the bdomen were normal with a large amount of fat; ıe heart showed some fatty infiltration, but was herwise normal; the brain showed vertical menin- tis extending down the outer and medial surfaces both hemispheres; there was no basal meningitis. r. Bowden's report gave meningitis as the cause of eath, and the jury returned its verdict accordingly. r. Samuel Brighouse, an experienced coroner, ghtly examined Dr. Bowden very carefully at the quest as to whether the vaccination had hastened contributed to the death, or whether death was in ıy shape or form in a great or small degree attri- ıtable to the vaccination. The witness was unable answer in the affirmative and consequently the ry, under direction of the coroner, could hardly ıve given any other verdict than that of "Death om meningitis," as already mentioned.

Chemist's Successful Appeal.

A brief report in the *Times* describes the appeal an Islington chemist from a conviction for selling ıiment of turpentine which did not conform to the rmula in the British Pharmacopœia. The Finsbury stices had convicted him of selling a drug which was ot of the nature, substance, and quality demanded the purchaser, and had inflicted a fine of £1. It as stated that the prescription employed by the ıemist's assistant was that contained in the London surance Pharmacopœia, a compilation stated to be rgely used by panel doctors. There had been no ggestion of fraud or dishonesty against the chemist, e prosecution being undertaken under the Sale of od and Drugs Acts on the mere ground that the ticle sold did not correspond in its composition with e standard which the purchaser might be deemed to pect. The London Sessions Court on March 9th ashed the conviction and remitted the fine.

(FROM OUR OWN CORRESPONDENT.)

The Drain on the Insurance Fund.

THE evening papers are talking of "a crisis in tional Health Insurance" or "drain on the Sickness nd." This looks like the language of panic. Not ıg ago the talk was of gigantic surpluses and of ull steam ahead on additional benefits." Now the ady but somewhat too simple explanation offered is se certification by insurance practitioners, or scrupulous insistence of panel patients. Prof. exander Gray, the political economist, whose long perience in the Ministry of Health and as a Member the Royal Commission entitle him to a serious aring, has written a long and well-balanced letter the *Scotsman* on "a grave crisis." He knows the mplexity of the whole financial system of insurance well to assign the whole drain on the funds to any single cause. Commenting on certain statements[1] by Dr. Vernon Davies in the recent House of Commons debate, Prof. Gray says:—

"Dr. Davies's view would apparently be that what we are now suffering from springs from an inherent vice in the panel system, that that system rewards the easy-going, the not over-conscientious, and the flabby. On that I may not express an opinion. But I think it is incumbent upon me to underline the gravity of the present position. The panel system, with free choice of doctor, represents in many respects the ideal, retaining so far as may be the essential features of private practice; but its operation calls on both sides for singular scrupulousness and high integrity. It ought not to be necessary to protest that efficient administration does not mean the refusal of just claims. No one desires that, nor would anyone scruple to give the insured person the benefit of any reasonable doubt. It is, however, tolerably clear that much more than that is involved, and that claims which ought not to be made are being certified and admitted. This, it must be remembered, constitutes an injury to all others who may in future be entitled to prefer a claim against the fund which is thus being improperly depleted."

Prof. Gray adds that the present serious drain on the insurance funds represents the gravest crisis that the insurance scheme has been called upon to face since it was launched in 1912, and that all those who desire to secure continuance of the panel system with its freedom and flexibility should realise the critical nature of the period lying immediately ahead—

"For assuredly no Government, of whatever political complexion, could tolerate a further increase in the claims rate without taking into consideration the efficacy of the administrative machinery, which makes possible such a continued and unexplained augmentation of the burden on the insurance funds. It is in the hope that worse things may be averted that I have ventured to address you."

Factors in Depletion.

So far as Scotland is concerned the reason for depletion are not very evident. For example, the expenditure on the drug fund does not keep pace with the expenditure on actual sickness. The medical referees are kept tolerably busy; but the percentage of their rejections does not differ very seriously from, say, 1925. The percentage of the "failed to appear" is pretty constant from year to year (1926 was, of course, exceptional for other reasons). If it be the case that the approved societies have lost confidence in the insurance practitioners' certificates, and if those practitioners themselves increasingly rely on the medical referees to certify "capacity," obviously the whole panel system is in some danger. The clash of public and private interest is bearing its evil fruit. The numbers sent to the referees may be due, not to increasing sickness but to this want of confidence. It is nonsense to think that a financial system that is at one moment overflowing with money is at the next in a state of "crisis." And we have to remember that, after all, a great part of the serious work that might and should have been covered by an insurance fund is done by the voluntary hospitals supported, largely, by the workers' voluntary levy. It is probable that, at least in the industrial areas, the continuance of unemployment is now, to a great extent, showing the results natural to impaired energies. In a time of relative dearth the organism cannot maintain the same tension as in the period of plenty and the margin of resistance is bound to lessen. But, however we look at it, the position is unsatisfactory. The present occasion seems to me a good one for initiating inquiry.

The Education Authorities Election.

The Scottish Local Education Authority candidatures are in full swing, and the tale of attendance at meetings is even more depressing than usual. Twenty years ago, in Edinburgh, medical examination and treatment of school-children attracted relatively large audiences, but this time all interest seems dead, and it is recorded that two candidates arranged a meeting to find that not a single elector appeared. What does this phenomenal indifference to local

[1] THE LANCET, Feb. 25th, p. 420.

government mean? In the counties the larger area may account for the smaller interest, but this is not true of the cities. Perhaps "proportional representation" is having an effect. There seems to be no mechanism for producing a sharp clash of opinion. One year, when a "religious" question had arisen in the Edinburgh School Board, the meetings were overflowing and 33 per cent. or so of the electorate voted—a record figure, I believe.

Are we to expect the elector's educational interest to awaken only in moments of creative reform? Are we to take the present indifference as a sign of the adequacy of the machine, or as a hint that the relatively "golden age" of the first quarter of the twentieth century is rapidly coming to an end? I remember vividly the first Scottish School Board election away back in 1872, when the State took over the work of the churches. Now the churches are concerned about union and, at least in some of the areas, the electors are quite unconcerned about education. On the other hand, a greater number of capable individuals all over Scotland are discussing education in all its phases with more vigour than I have ever known. Is the lethargy among the electors simply a phase of the moral and physical depletion following the war? or is our very imperfectly organised "democracy" capable only of mass interest when the question is outside the day's routine?

Candidature of Dr. James Kerr.

Dr. James Kerr, formerly of the London County Council (Education), who now resides in Edinburgh, is a candidate for the Edinburgh Local Education Authority. His unsurpassed record as a pioneer school medical officer gives him a very strong claim.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

What is Cell Research?

Dr. Michael Lenhossék, professor of anatomy and histology in the University of Budapest, recently delivered a lecture here in which he pointed out that the last two decades had brought about an almost epoch-making transformation in histological research. Purely morphological studies, carried out chiefly by means of fixation, hardening, and staining, have been supplemented by the science of experimental cytology and histology—the study of living cells and living tissues.

The progress made in this field, said Prof. Lenhossék, is due to a steady improvement in technique over a period of many years. Among the methods available are vital staining, micro-dissection, and micro-manipulation; but far more important than these is the cultivation of tissues, explantation, or bioculture. The study of cells and tissues in a "fresh" state could at one time be carried out only in the "surviving" period—i.e., in the short time which passes between their separation from the living organism and the first sign of decomposition. During this period the cells utilise their reserve energy, and although they sometimes reveal the phenomena of life, they are really dying. The pioneers of explantations conceived the idea of removing tissue elements from the living organism and keeping them alive, thus making possible their propagation, and in embyronic tissues their morphological development. Credit for the first successful experiments belongs to the American Harrison, professor of zoology at Yale, who made his pioneer investigations in 1904 at Bonn, in Germany, in the laboratory of the anatomist, Nussbaum. He placed the nerve sheath of the spinal cord of a young frog in clotted frog-lymph, and observed that the sheath, though removed from the living organism, not merely did not decompose, but even showed signs of development, inasmuch as new peripheral nerve-fibres grew out of it. This observation of Harrison's was of great importance, said Prof. Lenhossék, from the point of view of neurohistogenesis, but it was of still more importance in that it laid the foundations of explantation. At present research on these lines is conducted in almost every civilised country. It has been found that the cells and tissues of the embryo can be grown and propagated to an almost unlimited degree in suitable cultures, just as bacteria can be; and thus they are, in the strict sense of the term, immortal. All that is necessary is to supply them with adequate nourishment and see that metabolic products are removed.

Tissue culture, continued Prof. Lenhossék, affords a valuable means of investigating cancer; malignant cells can easily be cultivated in vitro, and meanwhile we are in a position to observe their different features. It has been shown that the cancer cells differ from other cells chiefly by their atypical metabolism, in consequence of which they are secreting particular enzymes; these ferments explain the destructive effects of cancer cells and their inroads into the adjacent tissues. If the culture medium were changed to correspond, ordinary cells also could be influenced in such a way that they would assume the features of cancer cells. By means of tissue culture it also has become possible directly to observe, under the microscope, the action of the different pathogenic bacteria upon living cells, and the reaction of the latter. By placing tubercle bacilli in a test-tube containing a culture of lymph nodes the process can be seen which takes place when tuberculosis bacilli are attacking the healthy tissues of a living organism and the formation of tubercles, or destruction of the bacilli, can be followed step by step. Tissue culture is very important also from the point of view of pharmacology, because the action of the different drugs and poisons can conveniently be studied in living cells cultivated in vitro. Again, in connexion with regeneration by formation of scars and connective tissue, it has been possible by means of culture to prove that the fibroblasts of the young connective tissues are formed from the leucocyte elements of the circulating blood. As a result of their experience with such methods some investigators doubt whether rigid discrimination is justifiable between the different varieties of cell (epithelial, connective tissue, muscle cells), and have started a theory that the cells are originally of one variety, and that the difference between them at a later stage depend entirely on the medium in which they find themselves. They support this view by pointing out that epithelial cells may, in a certain culture medium, assume the form and features of connective tissue. They acknowledge, however, that there are also unchangeable varieties of cell. It is to be hoped that this and other fundamental questions will soon be definitely solved with the help of tissue culture.

WESTMINSTER OPHTHALMIC HOSPITAL.—At the annual general meeting of the governors of the Royal Westminster Ophthalmic Hospital, the Earl of Arran announced that the new building will be opened for out-patients on April 10th, and that it is hoped to have the whole of the hospital in working order at the end of May or the first week in June.

LONDON LOCK HOSPITAL.—At the invitation of the board of management of the London Lock Hospital in the Harrow-road the Minister of Health has appointed a committee to inquire into the management and administration of the hospital. The committee consists of Sir John Eldon Bankes, chairman; Dr. John Fawcett, and Mr. H. J. Tennant. The terms of reference are: "To inquire into the management, administration and staffing of the London Lock Hospital, with special reference to the arrangements for the medical treatment of the patients and to the provision made for the moral, social, and material welfare of the inmates." In May last 8 of the 13 members of the Ladies' Committee resigned, and in July the London County Council gave notice of their intention to reduce the annual grant to the hospital by £2000 a year. The chief complaint of the ladies who resigned was that the matron, assistant matron, and another member of the staff had been dismissed without consultation with the Ladies' Committee. They also claimed that women ought to be elected to the board of a women's hospital. The management is in the hands of the board which consists solely of men.

"Audi alteram partem."

THE ASTHMA RESEARCH COUNCIL: AN APPEAL FOR FINANCIAL SUPPORT.

To the Editor of THE LANCET.

SIR,—The Asthma Research Council is preparing a ublic appeal for funds to carry out its object of ıcreasing our knowledge of asthma and allied ɔnditions. On the initiative of the Council a Medical dvisory Committee has been formed whose functions re to suggest what research work at present being ursued or projected should be supported by the ouncil, to indicate future lines of investigations, and) supervise such work.

The following preliminary suggestions have been ıade :—

(1) The formation of an asthma clinic at one or more ɔspitals, for the investigation of the "asthma-hay-fever-rticaria-syndrome."

(2) An investigation into the phenomena of sensitisation relation to asthma.

(3) An investigation into the nature of the asthmatic tack, from the physiological standpoint.

(4) An investigation into the relationship of asthma to neral respiratory diseases.

(5) An investigation into the family histories of asthmatic ıd allied conditions.

(6) An investigation into the nature of alleged "cures." his would include the continuation of the work of the ritish and American Medical Associations in investigating cret remedies.

(7) The provision of whole or part-time research scholar-ips and grants in aid for such investigations and for hers being carried out or projected by general practitioners, edical centres or research institutions, throughout the mpire, which are approved by the Medical Advisory ɔmmittee.

(8) The appointment, from time to time, of travelling vestigators to visit foreign clinics where investigations to asthma or allied conditions are being undertaken.

(9) The publication of any useful results obtained.

In order to carry out these schemes the Asthma esearch Council hopes to raise a fund of £50,000, ıd the Medical Advisory Committee trusts that embers of the medical profession will assist by inging to the notice of their patients—especially of ieir asthmatic patients—the aims of the Council and s need of support.

Subscriptions should be forwarded to the West-inster Bank, Ltd., Covent Garden, W.C. 2.

S. GILBERT SCOTT, London Hospital.
T. T. JEANS, Surg. Rear-Admiral (Ret.), (*Hon. Secretary*).

March 12th, 1928.

ONGENITAL HYPERTROPHIC STENOSIS OF THE PYLORUS.

To the Editor of THE LANCET.

SIR,—The question whether these cases should be eated by medical measures alone or by surgical ɔeration is one which is still unsettled. The lative rarity of the condition and the difficulty of tting groups of cases which are exactly comparable ıs hitherto prevented its solution statistically. The ctor which controls the surgical mortality above all se is the early recognition of the disease followed by ımediate operation. This I pointed out in a recent paper[1] based on 90 cases of the disease all treated by operation in the same institution. Of this group 15 were "private" cases and had suffered from vomiting on the average for 13 days—all recovered. The remaining 75 were "hospital" cases, and had an average duration of symptoms in fatal cases of 25 days; in these, the mortality was 48 per cent.

By whatever method the cases are treated, all observers have noted that the private case has a lower mortality than the hospital case; the earlier diagnosis in the private case appears to be the true explanation. Last year at the Birmingham Children's Hospital 44 cases of the disease were admitted; of these, 28 were operated upon with a mortality of 17·8 per cent., and 15 were treated medically with a mortality of 46·6 per cent. One case was moribund on admission and has not been included in either group. No selection of cases was made. In some units of the hospital all cases were operated on, in others, all were treated medically; in one case only was operation refused—the moribund case mentioned above which died within 24 hours of admission.

The interest of these figures lies, I think, in the fact that the two groups were drawn from the same geographical area and are therefore exactly comparable. The disease is relatively rare and appears to be rather unevenly recognised in various parts of the country. If this is so, then the mortality of the disease will vary with the source from which the cases are drawn, and will tend to diminish in any neighbourhood where recognition and early treatment becomes the rule. This improvement has been very noticeable in the area from which the Birmingham Children's Hospital draws its cases, for the surgical mortality has diminished from 40 per cent. in a group of 90 cases operated on in the years 1919–26, to 18 per cent. in 28 cases in 1927. Earlier recognition may be expected to diminish the mortality still further seeing that included in the above figures there were 21 "private" cases all operated on by the Rammstedt method and treated in the same institution with only one death, a mortality of under 5 per cent.

I am, Sir, yours faithfully,

Birmingham, March 8th, 1928. SEYMOUR BARLING.

COLONIC SPASM IN DIVERTICULITIS.

To the Editor of THE LANCET.

SIR,—In his Modern Treatment article last week, Mr. Gordon Bryan might have emphasised even more than he does the factor of spasm of the colon in diverticulitis, especially in those cases associated with stenosis. A few weeks ago I was asked to see an old lady of 80, in whom a progressively increasing constipation had been developing over a period of some six months. For three or four weeks she had not had a proper motion; the infrequent evacuations consisted of a few inadequate "rabbit droppings." When I saw her, she had for six days passed nothing by the rectum save occasional flatus; the abdomen was distended, and she was just beginning to feel a little nausea. Examination of the abdomen revealed a descending colon which could be felt as a very hard and moderately tender cord. A bismuth enema had, ten days previously, shown typical diverticula in the descending colon and the sigmoid.

I suggested dosing her with belladonna until symptoms of poisoning developed. She was given, therefore, 15 minims of the tincture every two hours, and watched carefully. In addition, an ounce of warm olive oil was carefully introduced into the rectum every four hours. She had been in the habit of taking liquid paraffin by mouth, and this was continued. In twelve hours she passed a good motion, and for the next three days she continued to pass a large quantity of fæces. Now she is living an ordinary, vigorous social life. Occasionally constipation threatens, but so far it has always been controlled by a return for a short time to smaller doses of belladonna.

[1] THE LANCET, Sept. 3rd, 1927, p. 492.

Spasm of the colon is very apt to develop in any condition of irritation or inflammation of the large bowel; and it is perhaps not enough recognised how large a part unsuitable diet plays in the maintenance of this condition. Especially does this seem to be the case when for various reasons imperfectly digested meat fibre reaches the large bowel, there to undergo putrefaction, with the production of offensive alkaline stools. It would appear that the products of the protein putrefaction may themselves irritate the large bowel; at all events, in many cases the forbidding of meat or fish, and the institution of a lacto-vegetarian diet (vegetables or fruit being given en purée) over a period of several weeks, produce even without the aid of drugs most satisfactory results.

Enemata in cases of diverticulitis should be regarded as somewhat dangerous weapons. In the first case of this disease which I ever saw, a "good enema" had been given—so good that it had evidently gone through one of the weak points of the gut wall, into the abdomen.—I am, Sir, yours faithfully,

Liverpool, March 10th, 1928. ROBERT COOPE.

GASTRO-DUODENAL ULCERATION.

To the Editor of THE LANCET.

SIR,—In your issue of March 10th your three correspondents appear to think that I am not in favour of the intensive alkaline treatment of gastro-duodenal ulceration. But I have used it continuously since 1919 and have written and spoken about its excellent results on numerous occasions. My advocacy of the treatment did not, however, prevent me from feeling distressed when one of my patients died in coma from alkalosis or from feeling satisfied when the recognition of the early symptoms—depression, anorexia, headaches, and nausea—in seven other cases may have saved them from a similar fate. Several deaths have been reported in America, and it is absurd for Dr. Cameron to speak about my "theory of alkalosis," or for Prof. MacLean and his colleagues to regard it as a "theoretical condition," simply because they have been fortunate so far in not seeing a similar case. It is admittedly rare, my eight cases representing about 2 per cent. in some 350 treated by this method.

Investigations are being carried out at Guy's Hospital and New Lodge Clinic with the object of eliminating the danger, and it is for this reason that it is important to study by modern physico-chemical and biochemical methods the effects of the different alkalis, though Prof. MacLean apparently thinks that such investigations are waste of time—a curious view for the director of a professorial unit. So far as we have gone, we believe that alkalosis can be prevented without any diminution in the favourable effect of the treatment by avoiding sodium bicarbonate and magnesium oxide and carbonate, all of which have the further disadvantage of stimulating the secretion of gastric juice after they have neutralised the acid present in the stomach at the moment of administration. If sodium citrate is given with each feed and the triple phosphates of magnesium and calcium (in proportions depending upon the state of the bowels) are given in powder form, the contents of the stomach can be kept permanently neutral, as we have been able to demonstrate by examining fractions taken at intervals throughout the day. The dose of alkali required is greatly reduced if the feeds are given hourly instead of two-hourly. It is difficult to see why Prof. MacLean advocated the use of bismuth oxycarbonate in his paper, as he now states that he realised that it does not act as an alkali under the conditions present in the stomach; or why he only referred to the anti-clotting effect of sodium citrate, although he knew that it was one of the most potent factors in the alkaline treatment he described.

American writers have laid great stress on the importance of pyloric obstruction and renal disease in connexion with alkalosis, but on looking into the details of the eight cases we have seen at New Lodge Clinic, I find that only one had any pyloric obstruction and only one any definite renal disorder. All the others had normal urine, a normal cardiovascular system and normal blood pressure, but two had a slight excess of blood-urea. In every case the blood-urea was much raised, though the urine remained normal, when the first symptoms appeared, this being doubtless a result and not the cause of the alkalosis as it fell rapidly when the treatment was discontinued.

Dr. Geoffrey Fildes states that it was assumed in the paper written by himself and his colleagues that "the present-day practitioner was sufficiently conversant with modern practice not to overlook such a obvious possibility of trouble" as oral sepsis. The fact remains, however, that, as I pointed out in my last letter, about 70 per cent. of the cases sent to the Clinic were found on expert dental examination to have oral sepsis.—I am, Sir, yours faithfully,

ARTHUR F. HURST.

New Lodge Clinic, Windsor Forest, Berks,

NEWSPAPER INSURANCE FROM A MEDICO-LEGAL POINT OF VIEW.

To the Editor of THE LANCET.

SIR,—When, recently, two London daily newspapers with a huge combined circulation (*Daily Mail* and *Daily Express*) decided to extend their free accident insurance benefits to include £100 for every fatal accident, it must have given some food for thought to many a medical practitioner. Was the fatal illness of to-day to become the fatal accident of to-morrow? After 20 years of the Workmen's Compensation Act, cases are still being fought out in the courts as to "what is an accident." In one case that went to the House of Lords it was laid down that "it might be just as serious to be hit in the eye by a single microbe as by a cricket ball." Newspaper insurance opens up a similar vista of difficulties. The strain of opening or closing a window on a person with a diseased heart might well be called an accident, especially if £100 depended upon the terminology used. The registrar of deaths or the coroner would probably have to use discretion in the matter.

I have recently been interested in "falling out of window" cases. They would appear to be on the increase. They occur in all sorts of places, hotels, institutions, private residences, and offices. In several cases an "open verdict" has to be returned owing to lack of evidence. Taken as a class, they might be the result of—murder, manslaughter, suicide, misadventure, accident, or sudden illness. A man might drop dead in a room beside an open window. If in doing so he happened to fall out of the window on to the ground below, it would be a difficult point to decide or prove the exact cause of death. It has no parallel to the case of a dead body thrown into the river to simulate drowning.

Newspaper insurance may add yet another responsibility on the already over-burdened medical practitioner.—I am, Sir, yours faithfully,

Old Broad-street, E.C., March 12th. J. J. SCANLAN.

DISPOSAL OF THE DEAD.

To the Editor of THE LANCET.

SIR,—The education of the public towards the ideal of cremation is slow, but it should not be difficult to instil into its mind at the present moment, when the conception of the ideal of health is developing that the dead are unclean and dangerous; that handling and kissing a body is revolting; that a "nice corpse" is an abomination, and not a thing to be made much of by friends and relations. In our temperate climate rapid putrefaction does not usually occur, and this tends to the belief that there is no danger in a body remaining in a house for a period up to a week. While it is difficult to prove that this danger exists, I think it is safe to assume

specially in view of the fact that the mouth and ose cannot be effectually closed, and that the earliest utrefaction occurs in the upper air passages.

There are two methods, I suggest, by which this anger could be averted. First, removal of the ody within 24 hours to chapels attached to ndertakers' premises, where refrigerating plant could e installed under the bier. Secondly, sanitation of he body within 24 hours. By this I do not mean mbalmment, but a simple and rapid replacement f the blood in the main vessels by a formalin or other ntiseptic solution. I consider that the medical ractitioner should definitely advise this in all cases here death has occurred through specific infectious evers, pneumonia, malignant disease, cardiac disease, ephritis, and in any disease where dropsy has ccurred; and point out to the relatives that he dvises this in order to protect the living.

One or other of these methods should be used hether the body is to be cremated or buried. Too aborate sanitation is not indicated, as it would tend prolong the time in which the body resolves itself to its natural elements. Both these methods, but rticularly the latter, would effectually lay that nnecessary bogy "premature burial," and this would e of great assistance to those to whom the idea of rial alive is a very real fear. I do not think that it ould take many years to instil these ideas into the blic, and I think that they should come primarily om the medical profession.

I am, Sir, yours faithfully,
C. BERKELEY WAY, M.B., B.S. Lond.

Finchley-road, N.W., March 9th, 1928.

FACIAL PAIN IN PULMONARY DISEASE.

To the Editor of THE LANCET.

SIR,—A case of pulmonary abscess associated with in referred to the face was reported in your columns st week by Dr. R. C. Hutchinson and Prof. J. S. B. opford. The absence of any reference by the thors to the work of Sir Henry Head on referred in in visceral disease suggests that a masterly ntribution to clinical medicine is less well known an it deserves to be. This may be explained by e fact that it is now over thirty years since it was blished in *Brain* (1893, p. 1; 1894, p. 339; 1896, 153). These three papers, however, are of such r-reaching importance, both for the diagnosis of sceral disease and for the correct interpretation of in, that no clinician can afford to leave them unread. With regard to referred pain in pulmonary disease, r Henry Head showed that, as in the case of other ra-thoracic and intra-abdominal viscera, disease the lungs may produce referred pain in two areas, e on the body and one on the head. In disease the pulmonary apex these areas lie in the third d fourth cervical segmental areas, and the nose d the middle part of the forehead. These are the uations of the pain in the case reported by Dr. tchinson and Prof. Stopford, in which the abscess s situated in the upper lobe of the left lung. Sir nry Head's interpretation of the reference of pain the head and face in visceral disease is based upon skell's observation that the vagus and the glosso-aryngeal nerves represent the visceral branches a set of nerves whose somatic sensory roots are be found in the sensory portion of the trigeminal. suggests that the impulses referred to the area of fifth nerve reach the brain by the vagus.

This explanation, if correct, would account for the currence of referred pain in the case reported, in te of the fact that the phrenic nerve had previously en resected. Moreover, it seems a more likely pothesis than that a close relationship exists tween the trigeminal and the phrenic.

I am, Sir, yours faithfully,
ondon, W., March 13th, 1928. W. RUSSELL BRAIN.

Mental Breakdown in Adolescence.—In Dr. J. B. Strafford vis's letter which appeared in our correspondence columns week the word in the fifteenth line, twice printed etermination," should read "deterioration."

Obituary.

HENRY WILLIAM LANGLEY BROWNE, O.B.E., M.D. BIRM., F.R.C.S. EDIN., LL.D. TORONTO.

Dr. Langley Browne, whose death took place at Birmingham on March 7th in his eightieth year, was held in high regard as a practitioner throughout the Black Country, and among his colleagues as one who cared much for the advancement of medical knowledge and prestige.

Henry William Langley Browne was born at Bishop Auckland, Co. Durham, on Nov. 28th, 1848, the son of Dr. Benjamin Stocks Browne. Soon after his birth his father, who had only qualified in 1844, removed to West Bromwich, where he practised during the remainder of his life. The son went to school at Edgbaston and Sydenham College, going on to his clinical study in Birmingham hospitals, and qualifying M.R.C.S. in 1870 and L.R.C.P. Edin. a year later. Immediately on qualification he joined his father in practice, adding another 50 years to the family connexion with West Bromwich. He soon obtained an appointment on the staff of the local hospital, to which he was attached for nearly 30 years, and becoming interested in surgical technique he communicated a number of articles to the medical papers on ligature of arteries, appliances for bloodless operations, and various types of industrial emergency. About this time he was appointed surgeon to the Great Western Railway, and was also acting as medical officer to the G.W.R. Provident Society. Though very busy as a practitioner in these and other directions, he found time to take the F.R.C.S. Edin. and all the medical degrees granted by the newly formed University of Birmingham. He also became an active member of the Birmingham and District General Medical Practitioners' Union, serving on its executive and ultimately presiding over its counsels. In 1893 he was elected to represent the Midland Counties branch on the Council of the British Medical Association, of which in turn he was chairman from 1906–08. At other periods he was president of the Midland Medical Society and of the Association of Factory Surgeons. In 1901 he was elected a member of the Council of the Medical Defence Union, giving valued assistance in that capacity until his election as a Direct Representative on the General Medical Council in 1906 compelled him to resign; he was returned at the head of the poll then and again at the general election in 1911, sitting on the Council until 1920. During his period of office he presided over the Unqualified Practice Prevention Committee set up by the Council in 1907, and his hand was seen in admirable reports presented to the Council by that committee in 1908 and 1911.

DR. LANGLÉY BROWNE.

The first report, made with the coöperation of the officers of the Council and of many official bodies, included a digest of the laws in force within the British Empire and in foreign countries designed to restrict medical practice by other than legally qualified persons, and was followed by a supplementary statement from Dr. A. G. Bateman, the late secretary of the Medical Defence Union, drawn up from the Statutes of the different provinces in Canada and of the different American States. The report formed an admirable synopsis of the professional status of medicine in the civilised world, and in submitting it to the Council Dr. Langley Browne moved that "as the present Acts did not sufficiently enable persons requiring medical aid to distinguish qualified from unqualified practitioners the Government should be requested to take steps for the appointment of a Royal Commission to inquire into the evil effects of unrestricted medical practice by the unqualified. The motion was agreed to, and the substance of the report and the attitude of the General Medical Council received wide commendation. Although no Royal Commission was appointed, there is no doubt that Dr. Langley Browne's report focused public as well as medical attention upon weaknesses in the existing Medical Acts.

During the period of the war, though in the late sixties, Dr. Langley Browne took charge of the Churchfield Red Cross Hospital at West Bromwich, and placed his intimate knowledge of general practice and practitioners at the service of the Central Medical War Committee. Two years later he retired finally from practice as the result of an accident which deprived him of his eyesight, but not of his continued interest in medical affairs.

One of his colleagues writes of Langley Browne as a man of high principles who vigorously opposed all unethical practices. No one in the district was held in higher respect or more thoroughly deserved the confidence of professional colleagues, and his enforced withdrawal from active work was deplored by a wide circle of medical friends and patients.

Dr. Langley Browne was a life member of the governing body of Birmingham University and a justice of the peace for the county of Stafford. Toronto University made him a hon. LL.D. He married Gertrude, daughter of R. Heckels, of Sunderland, by whom he had one daughter.

Public Health Services.

REPORTS OF SCOTTISH MENTAL HOSPITALS.

THE 1927 reports of the *Aberdeen* and *Glengall* mental hospitals have reached us with commendable promptitude, following by only a short time the 1926 reports of some other institutions. On the last day of 1927 there were 799 patients on the *Aberdeen* register, including 44 voluntary boarders, one of them rate-aided. The recovery-rate for the year was 31·67 per cent. and the death-rate 8·21 per cent., a reduction on the average for the past 30 years. Six of the 65 deaths were due to general paralysis and 12 to phthisis. The malarial treatment has proved satisfactory, and protein shock therapy has also been tried for general paralysis. Ninety-two patients had ultra-violet rays from a mercury-vapour lamp and all gained in weight. Some of the melancholic patients improved mentally. The dentist treated 162 patients, and reports that he found a marked improvement in oral conditions compared with the previous year. Diathermy gave gratifying results in cases of sciatica and lumbago. 102 patients were examined for diagnosis under the new X ray plant, and a high-frequency apparatus has just been installed. The occupational therapy department has been enlarged, and two handlooms are to b set up. A detached pavilion is being erected for fema tuberculous patients.

There were 602 patients in the *Glengall Hospita Ayr*, on Dec. 31st, 1927, of whom 11 were voluntar boarders. In 20 per cent. of the cases admitted th mental disorder was associated with some form serious bodily illness, and 40 per cent. of the admissio were in a precarious state of health. Nearly two-thir were free from hereditary taint as far as the histori could be relied on—a figure which must bring th admissions very nearly into line with the gener population. The recovery-rate was 27 per cent. f men and 34 per cent. for women, a decline which reflec the large number of incurable cases admitted. Th death-rate was 12 per cent. and autopsies were he on 64 patients. The phthisis-rate was high and number of inmates died from general paralysis. Th general health was good. Parole is allowed freel and parties are sent to cinemas, concerts, and footba matches. The Visiting Commissioner comments the free homely atmosphere of the wards and th excellent arrangements for classification, with absen of noise and restlessness. Only 136 of the patien were unemployed at the time of his visit. Five nurs and one attendant gained their R.M.P.A. certifica during the year, bringing the total certificated up 44 per cent. of the women and 40 per cent. of the me

The *Roxburgh* District Board of Control had 3 patients resident in their asylum at the end of th financial year 1927, an increase of ten. Of the s voluntary boarders admitted during the year one w rate-aided. The recovery-rate was 34·4 per cent., figure which is kept low by the apparently increasi practice of sending senile persons to the institution a practice against which the medical superintende protests strongly. The death-rate was 7·6 per cen and autopsies were held in 17 cases. A small epiden of influenza in the spring caused no serious anxie A visiting dentist started work during the summ Two new verandahs are greatly benefiting new admitted patients. The Commissioners note that commendable attention is paid to the idiosyncras of individual patients in the matter of diet.

The *Stirling* District Board of Control report steady increase in the numbers of patients at th *Larbert Mental Hospital*. The total number under th Board's supervision at the end of the financial ye 1927 was 1226, of whom 897 were in the institutio Of all those admitted only 32 were classed as being average health. Twenty-three were suffering fro senile insanity, 15 from general paralysis, and 8 w mentally defective. Twenty voluntary patients w admitted during the year, of whom nine were ra supported, so that the Stirling parish councils appe to be more up to date in their views than other pa of Scotland. The medical superintendent points o that, as no grant has been paid in respect of a certifi patient since 1916, the parish councils lose nothing sending voluntary patients to mental hospitals. Th recovery-rate was 37·43 per cent. One of the m discharged had been a melancholic for 12 yea Eight patients were sent out on trial and only two h to return. The death-rate was 9·4 per cent., th lowest for some years. A post-mortem examinati was held in every instance where permission w granted. General paralysis was the cause of death 17 cases and phthisis in seven. Enteric caused anxie in the spring, but otherwise the general health w good. No carriers were found. New patients a admitted to verandah beds in the reception hospit and the method is found highly satisfactory. Six eight patients were treated by the electrical instal tion, and many derived benefit from Schnee bat high frequency, and artificial sunlight. A tungst arc has now been provided for local treatments. Th visiting dentist saw 215 patients during the ye and reports that very few of the recent cases sh healthy mouths. An occupational therapy departm has been started, and rug-making, raffia, and bask work are taught. The old admission hospital h been turned into an open-door home for convalesc

nd parole patients, and is greatly appreciated. hronic industrial patients are now accommodated in nother separate block, and a third takes the sick and nfirm, with a department for the tuberculous and one r epileptics and troublesome patients. Most of the ilk for the institution comes from the home farm, nd new byres are to be erected. 3086 eggs were rovided during the year from the poultry farm, and he gardens, while showing a balance of £1076, rovided all the vegetables and flowers needed. Fifty- our members of the nursing staff hold their certificate, n of whom passed the final during the year.

The *Inverness* District Asylum housed 723 patients t the half year 1927, an increase of 17 on the previous ear. The recovery-rate was 26·3 per cent. and the eath-rate 9·5 per cent. Phthisis and senile decay ccounted between them for 47 per cent. of the fatal ases. Autopsies were performed in eight instances. uring the year 15 patients were sent out on trial. nly 16 of the 141 who have now gone home on robation have had to return to the hospital. There as an influenza epidemic in March, but otherwise the eneral health was good. Many of the male patients ork in the garden and farm, and the supply of milk, otatoes, and vegetables has been adequate for the eeds of the institution. Eight nurses and one tendant gained their certificate during the year.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 3RD, 1928.

Notifications.—The following cases of infectious isease were notified during the week :—Small-pox, 35 (last week 392) ; scarlet fever, 1711 ; diphtheria, 481 ; enteric fever, 28 ; pneumonia, 1572 ; puerperal ver, 37 ; puerperal pyrexia, 114 ; cerebro-spinal ver, 14 ; acute poliomyelitis, 6 ; acute polio- ncephalitis, 2 ; encephalitis lethargica, 33 ; dysen- ry, 9 ; ophthalmia neonatorum, 118. No case of holera, plague, or typhus fever was notified during he week.

The cases of small-pox were notified from the following counties :—London, 2 ; Bedford, 1 ; Berks, 1 ; ambridge, 1 ; Chester, 4 ; Derby, 13 ; Durham, 83 ; loucester, 2 ; Hertford, 1 ; Lancaster, 38 ; Leicester, 1 ; incoln, parts of Lindsey, 2 ; Norfolk, 1 ; Northumberland,) ; Nottingham, 12 ; Oxford, 1 ; Southampton, 1 ; Staf- rd, 4 ; Suffolk East, 1 ; Warwick, 14 ; Yorks, North iding, 9 ; West Riding, 74 ; Brecknock, 1 ; Glamorgan, 4 ; Monmouth, 44.

The number of patients in the Infectious Hospitals of the etropolitan Asylums Board on March 6th–7th was as llows :—Small-pox, 11 ; scarlet fever, 1682 ; diphtheria, 315 ; enteric fever, 28 ; measles, 1460 ; whooping-cough, 55 ; puerperal fever, 13 (plus 11 babies) ; encephalitis thargica, 71 ; poliomyelitis, 1 ; "other diseases," 31. t St. Margaret's Hospital there were 15 cases of marasmus, 2 babies (plus 3 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including ondon, there was 1 death from small-pox, 2 (0) from nteric fever, 167 (89) from measles, 4 (1) from scarlet ver, 41 (16) from whooping-cough, 47 (10) from diph- heria, 51 (7) from diarrhœa and enteritis under two ears, and 93 (21) from influenza. The figures in arentheses are those for London itself. The deaths om enteric fever outside London were reported from ristol and Warrington. Of the 78 fatal cases of easles outside London, 19 were reported from lymouth, 12 from Sheffield, 7 from Manchester, 6 om Derby, 5 from West Ham, 4 each from Bristol nd Worcester, while the figures from Glasgow and ublin for the same week were 15 and 10 respectively.

Small-pox Deaths.—We learn from Dr. W. Campbell yons, medical officer of health for South Shields, hat since Feb. 21st four deaths of small-pox patients ave been reported in the county borough, the articulars of which are as follow :—

1. A woman, aged 30, vaccinated in nfancy, was notified s a small-pox case on Feb. 21st and removed to hospital n that day. Onset Feb. 14th, rash Feb. 20th. On dmission to hospital her temperature was 100°F., about our hours later it was 103°, and at the time of her death, about 6 A.M. on Feb. 22nd, it was 107°. The death was certified as : (1) ulcerative endocarditis, (2) small-pox.

2. A female infant, born prematurely (7–8 months) on Feb. 4th, admitted to hospital on Feb. 25th, rash Feb. 24th. Onset unknown ; unvaccinated ; died on March 1st. Death certified as : (1) premature birth, (2) small-pox.

3. A woman, aged 66, notified as small-pox and removed to hospital on March 3rd. Onset Feb. 28th (?), rash March 3rd ; supposed to have been vaccinated in infancy, but marks not apparent. She was in frail health and as the home circumstances were very bad she was removed only after careful medical examination. She died six hours after admission to hospital. The cause of death was certified as : (1) senility or debility, (2) small-pox.

4. A boy of 6 years, unvaccinated, died on March 4th before any notification of the disease had reached the department. Onset Feb. 28th, rash March 4th. From an examination of the body the assistant M.O.H. formed the opinion that the case was one of small-pox, of hæmorrhagic type, and the private medical attendant has given a certificate in these terms.

In regard to the death from small-pox reported from Bradford in the return for the week ended Feb. 25th, we understand from Dr. J. J. Buchan that the patient was a man of 54 admitted to the Bradford small-pox hospital from outside the district. On admission to the hospital he was suffering from hemiplegia and diabetes, with diabetic gangrene of the toes, and Dr. Buchan adds that, in his opinion, small-pox was a factor of small contributory importance to his death. He had been vaccinated in infancy.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt. A. de B. Joyce to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Capts. to be Majs. : D. G. Evans, D. C. Scott, W. E. K. Coles, J. E. Brooks, W. J. Robertson, D. Fettes, E. Underhill, W. G. D. McCall, R. F. Walker, L. M. Rowlette, M. B. King, H. S. Moore, L. S. C. Roche, and B. L. Davis.

C. V. D. Rose, late Flight Lt., the R.A.F. Med. Serv., to be Capt.

ARMY RESERVE OF OFFICERS.

Maj. G. Baillie, having attained the age-limit of liability to recall, ceases to belong to the Res. of Off.

SUPPLEMENTARY RESERVE OF OFFICERS.

Lt. W. Boyd resigns his commn.

TERRITORIAL ARMY.

Maj. J. Allan, having attained the age-limit, is retd., and retains his rank, with permission to wear the prescribed uniform.

Lt. C. M. Bradley to be Capt.

INDIAN MEDICAL SERVICE APPOINTMENTS.

A certain number of appointments to permanent commissions in His Majesty's Indian Medical Service will be shortly made. Full particulars may be obtained from the Military Department of the India Office, Whitehall, S.W.

SMALL-POX LEAVE RESTRICTIONS.

A Fleet Order has been issued recapitulating the restrictions on leave of officers and men proceeding to any town or district in which an outbreak of small-pox has been notified. In the November list 25 towns and districts were mentioned. These places now number 58. The recent additions embrace Abercarn U.D. (Mon.), Birmingham C.B. (Warwick), Clayton U.D. (Yorks), Felling U.D. (Durham), Foleshill U.D. (Warwick), Kiveton Park R.D. (Yorks), Sheffield C.B. (Yorks), and Spennymoor U.D. (Durham).

DEATHS IN THE SERVICES.

Colonel Sir Robert Neil Campbell, I.M.S. (retd.), who died at Lahore on Feb. 18th at the age of 73, was educated at the Edinburgh Institution and at the University of Edinburgh. He joined the Indian Medical Service in 1877, and served in the Naga Hills Expedition of 1879–80 (mentioned in dispatches and medal), and also in the Akha Expedition of 1883–84 (mentioned in dispatches). He then served as Civil Surgeon at various stations in Bengal, and received the Kaisar-i-Hind gold medal in 1900. In 1909 he was appointed Inspector-General of Civil Hospitals in Eastern Bengal and Assam, and on the reconstitution of Bengal was gazetted to Assam as Inspector-General of Civil Hospitals and Prisons and Sanitary Commissioner.

Col. Campbell, who retired in 1914, had charge of two of the hospitals established at Brighton during the war for Indian soldiers. He received the C.I.E. in 1909, the C.B. in 1912, and the K.C.M.G. in 1917.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Invaliding in the Royal Navy.

On March 7th Sir Bertram Falle in a logical speech moved that the rules by which disability from disease is attributable to or is aggravated by service in the Navy should be re-examined, as well as the manner in which those rules are interpreted. He pointed out that the percentage of rejections among intending recruits is so high as to show that the naval ratings are the pick of the country, while at the same time removal from the Service for tuberculosis is frequent. This he considered could only be accounted for by the unhygienic nature of the employment, especially the sleeping facilities. The Survey Board in charge of the removals found themselves able to hold that tuberculosis was attributable to or aggravated by occupation in but a small number of cases—the percentage, he admitted, had gradually risen from 3 and 4 per cent. to 10 per cent.; but considering the circumstances of recruiting he held that the percentage should be much higher, while he pointed out that discharge without admission of liability, where the term of service had been less than ten years, would mean deprivation of pension. Sir Bertram Falle, while disclaiming any intention to belittle the medical profession, considered that a purely medical Survey Board, such as has existed since 1914, does not work so well as the previous arrangement whereby the president of the Board had to be a Captain R.N. (executive) for the ratings did not place the same confidence in the decisions. He held that a Board of Appeal should be granted both to rank and ratings before discharge for tuberculosis. Rear-Admiral Beamish, in seconding the motion, confirmed Sir Bertram Falle's view of the dissatisfaction existing, and pointed out that the rate of tuberculosis among the naval ratings is higher than that in the Army or in the civilian population, and was higher among the ratings than among those of officer's rank. He cited from personal experience facts to show that disease could only too easily be acquired during service in the Royal Navy, and he urged that the existing rules should be looked into, so that the State might get a clear idea of its responsibilities in the matter. Some method of insurance, perhaps on a contributory basis, might meet the circumstances. Mr. Ammon associated the Labour Party with the motion, and pointed to the remarkable diminution of tuberculosis in the post-office as showing what might be done. Dr. Vernon Davies informed the House how tuberculosis differed from certain other pathological conditions, when assessing the measure of disability or aggravation entailed by occupation was in question. He pointed out the practical difficulties involved, and indicated that a scheme of compulsory insurance for the Service against tuberculosis might meet the difficulties. Lady Astor joined in Sir Bertram Falle's contention that there should be a right of appeal from the decisions of the Survey, but the House was "counted" before a division was reached. It is felt by all parties that men invalided from the Navy should have all the circumstances closely scrutinised, and the subject should engage the attention of the House again at an early opportunity.

Army Estimates.

On March 8th Sir L. Worthington-Evans (Secretary of State for War), in moving "That Mr. Speaker do now leave the Chair on the House going into Committee on the Army Estimates, 1928," said that this year he was asking on Vote A for 153,500 men, or 13,000 less than last year. Economies had been made in the administrative services, principally in the Royal Army Service Corps and the Royal Army Medical Corps. The total amount which he was asking the House to vote was £41,050,000, or a net decrease of £515,000, as compared with last year. But owing to other causes the true saving to the Exchequer was £1,000,000.

Mr. Lawson said that there was a very significant fact which was worthy of the attention of the House, the War Office, and the country generally. It was that 84,000 recruits offered themselves last year, and out of that total about 28,000 were accepted as meeting the standard of physical fitness required for Army purposes. They had to put that side by side with the fact that the Secretary for War had stated that the Army was below standard, and that there was need for further men. He asked the House to consider what must be the real state of affairs among the civilian population if they saw a continually increasing standard of physical fitness demanded in regard to men who offered themselves for service. Last year the proportion accepted was 35 per cent., compared with 33 per cent. this year. Coming as he did from the homes of the masses of the people he said that there was very little hope in view of the present standard of life of an improvement in that direction during the next few years.

The motion "That Mr. Speaker do leave the Chair" w agreed to, and the House went into Committee of Supply the Vote for men.

Unqualified Dispensers.

Sir Wilfred Sugden said a conference sat in 1920 co prising representatives of the technical officers of the W Office who carried the responsibility of the supervision unskilled dispensers employed in hospitals and delega from the great body of organised pharmacists. T conference considered the proposals of the skilled men w were willing to undertake the responsibility of dispens in the Army, the field hospitals, and in the home hospit of drugs and other necessities. But nothing was done utilise all this expert knowledge which was patriotica offered to the defensive forces of the Crown, and pa cularly to the Army. The Navy utilised the services the skilled pharmacists to the full, and every country Europe followed the same practice. The first suggest made to the conference in question was that there sho be a commissioned officer in charge of every accredi military hospital in the country. It was contended t there should be three commissioned officers for a cert area in London. Next it was proposed that there sho be given full facilities for the unqualified dispensers w had been operating under medical supervision to qual The pharmacists were prepared to give special facilit for these men to acquire the necessary education to d with this important work. The recommendations of t conference had never been accepted in the slightest deg by the Army Council or by the Secretary of State, althou the representatives of the Army Council and the Secret of State had accepted those resolutions unanimously. was agreed by the conference that the appointment of th pharmacists would be an economical arrangement. T War Office at the present time were buying their necessa compounds already prepared, but if these could be ma up under the control and supervision of trained pharmaci there would be on the market prices of the 12 or 13 standa compounds which were necessary in the military hospit of this country a saving of from 50 to 70 per cent. of cost. If it was contended that economy through utilisation of unskilled labour in the hospitals was perfec covered and made fool-proof by medical supervision, wished to say that while paying his full quota of resp to the medical profession it was impossible for them control and guide and prevent any error that might a in dispensing and at the same time to secure cheapness the product. He had obtained from the University Cambridge details of the necessary qualifications of a n trained in chemistry in 1913 and also in 1927, and wh he compared the training given to the medical profess in pharmacy with that which was called for in the case certificated pharmacists he said that it was impossible the medical profession, while at the same time acting physicians and surgeons, to give the necessary guidance unskilled men in administering and dispensing medicin Either the medical or the pharmacist work must suff While criminals and civilians could demand that th medicine should be mixed by trained chemists, and wh lunatics were treated in the same way, the ordinary sold had his "number nines" prepared by those who w untrained for the work. They only asked that there sho be not less than one commissioned pharmacist, possibly senior rank, supported by an officer of junior rank in ea Army hospital at home and abroad with a senior co missioned pharmacist officer at the War Office. If th was not possible then an officer of senior rank should oper under the medical officers in each hospital at home a abroad.

Mr. Kirkwood moved to reduce the vote by 50,000 m

Reduced Strength of the R.A.M.C.

Sir Richard Luce said that he did not approve of t reduction of the vote, but he wished to raise several poi in regard to the Royal Army Medical Corps. First, th was a reduction in the estimates this year in the establi ment of that Corps of 22 officers and 284 men. That w out of an establishment of 4163, a reduction of about 6·8 cent. The reduction in the rest of the establishment of t Army was only about 1000 out of an establishment of abo 140,000, or about 0·7 per cent. This was only one-ter of the percentage by which the Royal Army Medical Co was to be reduced. It was mentioned in the estimates th this reduction was due to the closing down of certain hospit and a recent review of the number of equipped beds ma tained in military hospitals. He had no objection to t reduction of hospitals where that could be effected, or to coördination of hospitals where that could be done betwe one service and another, as had been done to some exte in the last year or two. He was one of those who believ that the medical services of the Army, Navy, and Air For would be benefited by the amalgamation of those service but the reduction of hospitals must not be the criterion

he establishment of the Royal Army Medical Corps. If he strength of that Corps were to depend solely upon the umber of beds, and if the duty of the medical service were nerely to look after the sick of the Army in peace-time, a nuch better system than the present one could be devised. Vhy should they have men of the Royal Army Medical 'orps doing duty in military hospitals at all? Such work ;ould be infinitely better done by women nurses and sisters. 'he duty to be done in these hospitals was the training of he male personnel for duty in war, and that duty could ot be done by women, for it was largely work in the field, lthough they knew how much work women did in the late ar close to the front. Therefore the establishment of the toyal Army Medical Corps must not be allowed to be based n the actual beds that were required in hospitals in peace-me. The proportion of men needed by the Corps as com-ared with other branches of the Service was based on the xperience of many years going back to the beginning of st century. Time after time as wars had come there had een difficulties, because in the intervals between those ars, through undue economy, the medical services had een reduced below the level of safety and efficiency, and is had rendered them incapable of doing their work in me of war. The work of the Royal Army Medical Corps the last war showed what had been gained by experience previous wars, and the Corps rose nobly to the occasion. here was practically no serious breakdown in any part hich had to be worked by that Corps, although there was partial breakdown in Mesopotamia where the medical ork fell on a branch of the Service—the Indian Medical ervice—which had been starved in peace-time. At the id of the war the Corps had been proved and was not found anting, but since then with the cry for economy there had en a perpetual and constant whittling down of the Service. 1923–24 there was a reduction of over 300 men; a year fore a reduction of 63; and this year there was another duction of 300 officers and men. There was an idea that edical service could be improvised in war-time out of vilian medical men. That was not a fact. Anyone who id had experience in the Great War realised that where ey had to deal with officers and men who had not received administrative training in medical work for war it took em a long time before they achieved anything like the ate of efficiency which was attained by Regular officers. ere were many branches of the medical service which re not the same in peace as in war. Medical sanitation is a complete service of its own, and required a different owledge and experience from that acquired in peace-time. reductions in the cost of the Army were necessary and ductions in the medical services were made, they ought be in proportion to the reductions in the other services.

The Upkeep of Military Hospitals.

In Vote 10 there was a sum of £69,000 for new buildings the various hospitals throughout the Empire—all very cessary improvements and additions to the hospitals, but was to their upkeep that he wished to call attention. It is impossible from the Estimates to see how much of the ,314,000 which was to be devoted to the upkeep of military ildings was to be devoted to hospitals. Last year circum-nces took him to the great hospital at Netley. One could t go to that hospital with its great traditions founded as was in that wave of military medical ardour after the imean War on the most beautiful site of Southampton ater, and see it as it was now without a sense of depres-n and gloom, and without feeling that they were not ing their duty to the sick soldiers in peace-time. Netley s the largest military hospital, and it was specially voted to men invalided from overseas. They went there find it in an atmosphere of gloom, a lack of paint and a k of care, the grounds allowed to go to rack and ruin, d this was in a place where everything might be the very st possible. He appealed to the Secretary of State to k into this matter of the upkeep of the hospitals. It uld do a vast amount of good if the right hon. gentleman uld visit them, and perhaps before doing so he might it a good voluntary hospital and compare the difference atmosphere. A year or two ago one of the greatest thorities on hospitals in this country said in his hearing—t with reference to military hospitals, but with regard to ier State hospitals—that as long as a department was nected with the State bare duty might be done, but no ice would be added to that duty and there never could a heart-beat in a Government department. They did want that to be said of the military hospitals. He did think it was so in war-time, but since then things had n drifting in such a way that they were not very far m that statement being true in regard to the military pitals.

New Candidates for the R.A.M.C.

There was also the important point of the failure to p up the establishment of the medical officers in the vice. He knew that that was an extremely difficult nt, and it was not at all easy to say why the Service failed to attract duly qualified men at the present time. Looking at it from a fair point of view he could not say that the pay of the Royal Army Medical Corps was insufficient, but the fact remained that there were not enough candidates coming forward and the Service was lacking in efficiency on that account. He thought that one of the chief causes was the feeling in the Service that it was a service that was being reduced and one which had not the sort of permanency necessary to keep up a feeling of esprit de corps. The constant reduction of strength and therefore the increase of work, was causing unrest among those who were already serving, and making them unwilling to get other men to join. He had felt it his duty to warn the Secretary of State against allowing this Service to go downhill by reason of a series of piecemeal reductions. The medical officers and their heads in the Army had not got the weight of power behind them to stand up for their particular share of the available money in the Estimates as had other departments. It was the duty of someone to bring to the notice of the Government and the country the fact that they were not getting their fair share, and that they were likely to be reduced below a state of efficiency. They had no direct representative on the Army Council, but only shared one with a very large number of other branches of the Service, and therefore they could never make their position known in the same way as if they had a representative of their own. If in years to come another war took place and the medical services were found unprepared or incomplete, the country would call out for blood as it had done on other occasions. Somebody would have to be made the scapegoat. Whoever it might be the chances were that the scapegoat would not be the Secretary of State of that time or any other Minister, but the heads of the medical departments would have to bear the brunt of the responsibility for what was being done now in piecemeal reductions of the Service. He therefore urged that while reductions and economies must be carried out, their application in a service so essential as the medical service should be in proportion to the reductions of other branches of the Service.

The Power of Expansion.

Lieut.-Colonel FREMANTLE said he wished to support what had been said by Sir Richard Luce in regard to the medical services. He thought that the medical members of the House could rightly plead for an extension of services in some directions, because they had supported economies in other services. On several occasions during the last nine years he and other medical Members had urged the futility of keeping up general hospitals for both the Army and the Navy in peace time at the same place. After several years, and following the reports of various committees, they had at last seen the reduction of these general hospitals one by one. It was a very difficult matter, and had to be done very cautiously and carefully in order that there might be no permanent damage, and that they might still have the power of expansion in case of need. But there was still room for further economy in that direction, and it was in that sense that the medical Members of the House urged the Government to continue on that line of economy. They felt, however, perturbed when economies were made in the machinery for expansion in case of need. The medical services consisted of two parts. The greater part consisted of physicians and surgeons—the tactical part which could to some extent, especially in connexion with the Territorial Army, be improvised in case of war. He meant that it could be imported from the civilian services. But there was the other part, the administrative part, the nucleus of each unit, which could not be so imported unless it had been trained. It had been suggested that the establishment of the Territorial Army must be cut down in peace-time, including the medical service, and despite representations from himself and his colleagues in the House the number of field ambulances to a Territorial division was cut down from three to one. That was a very serious thing. It meant that when the Territorial Army mobilised again expansion would be difficult. The reduction, he maintained, was excessive. The personnel of the Territorial Army medical services was down by one-third of its full strength. In the Regular Army they had still the difficulty of recruiting. A list published in the *Times* showed that they had managed at last to get 15 medical officers, as compared with the 60 that were required. They could not possibly support an army in the field unless they had an adequate supply of medical officers trained for their work. He urged the Government to pursue the work of securing recruits for the medical service. The real difficulty was not simply the question of pay, but the fact that the men now in the Service were overworked abroad, and instead of getting leave they were constantly kept at work beyond their time, the senior men being relied on to do comparatively junior work because there were no junior officers in the Service, and they were deprived of a great deal of their family life when they were getting towards the end of their service. These men did not give a good name to the Service

at home, and that made it all the more difficult to get the junior men. The medical service was a key service to the human machine, and it was essential to maintain these key services at the highest pitch.

The Soldier's Teeth.

Mr. MITCHELL BANKS said that whether the soldier's job was right or wrong nobody since the days of Homer had any doubts as to the value of the doctor. The soldier had three vulnerable points—his toes, his tummy, and his teeth. He thought that every doctor would agree that many of the intestinal complaints which soldiers suffered in India and Mesopotamia could have been prevented if only the teeth of the men could have been better looked after. He hoped that the Secretary for War when he was considering the medical aspect of the Army would not forget that unless they gave the soldier adequate teeth with which to consume his very healthy rations he was certain to fall a victim to rheumatism or to stomachic complaints.

Can the Medical Services be made more Attractive?

Dr. VERNON DAVIES said that he wished to associate himself with the speech of Sir W. Sugden in respect to pharmacists in the Army. The authorities at the War Office had taken the very definite position that the soldier in the British Army could be competently looked after by dispensers who had a small amount of training in the compounding and mixing of drugs, and they thought that the training of these men was sufficient to enable them to look after the medical needs of the soldiers. They might be right, but the Navy did not agree with them. The National Health Insurance administration under the Ministry of Health insisted that anyone who dispensed for the civil population must be a trained pharmacist. The Home Office had decided that prisoners in gaols must have their medicines dispensed by trained pharmacists. The War Office was alone in the attitude which they had adopted on this matter. If the War Office were right they should simply scrap all the pharmacists in the Navy, prison service, and National Insurance organisation and get the work done by cheap dispensers. If, on the other hand, the War Office was wrong, they might perhaps some day be inclined to consider the advisability of coming into line with the other services of the country. An army without an efficient medical service was of no use whatever. Had the Secretary of State done anything to see if that service could be made more attractive to medical men? Unless the War Office tackled this question seriously they would get into difficulties. The War Office had to remember that they were competing with panel practice and with all the public medical appointments in the country. When a young medical man soon after he had qualified could go into public medical service and work five days a week for £700 or £750 a year he had no definite inducement to go into the Army. A short service in the Army with either an increased gratuity at the end of the seven years, or preferably with retired pay, giving the War Office a call upon him at any time, would increase the popularity of the Service. If it could be arranged that any medical man who had served in the Army should have preferential treatment in applying for any State or municipal medical appointments that would make the Service still more popular.

Reply to the Debate.

Sir LAMING WORTHINGTON-EVANS, replying to points raised in the debate, said that to-day the dentist in the Army was not received with scoffs and scorn, but with open arms. There were 337 dentists and their assistants, and so well were they thought of that 16 had been added to their number in the course of the year. With regard to the pharmacists in the Army, the War Office had accepted some of the recommendations of the Committee which inquired into the matter. The recommendations which they were unable to accept would have involved a great deal of extra expense. The Government were of opinion that dispensing in the Army was carried out adequately and economically so far as the needs of the Army in peace were concerned. The Royal Army Medical Corps dispensers received adequate training for the work which they were called upon to do. As regarded the question of the Royal Army Medical Corps which had been raised by Sir Richard Luce and Colonel Fremantle, the reduction in that Corps was due to the closing of military hospitals in Cosham, Devonport and Chatham, and there was therefore a reduction in the number of equipped beds required. Owing to a closer coöperation with the Navy, military patients were now in certain cases treated at naval hospitals. The Committee which had been working on this question had enabled them to reduce the number of patients, and that accounted for the reduction of 22 officers and 271 other ranks. As a matter of fact, although that reduction appeared in the estimates, some of that medical personnel had gone to China and were carried on the supplementary estimate. Nevertheless, it was a reduction which was inevitable. In regard to the military hospitals, he (Sir L. Worthington-Evans) had visit most of the big hospitals in England, and he did not kn how it could be said that the Government were doi only their bare duty if the hospitals were good and we looking after the patients properly. Sir R. Luce had co plained of the gloomy atmosphere of these hospitals a of the absence of paint. That really was not the test o hospital; the real test was the medical service, and ev the social service which the patients received in th hospitals, and his experience of the Army hospitals he h visited was that they were not gloomy, that it was a gr deal more than the bare duty which was being done, a that real human attention was being given to men w seemed happy in the hospitals and content with the tre ment which they were given there. Sir R. Luce seem to suggest that the medical service was treated as a C derella service, that cuts were made in it out of proporti to the cuts made on the rest of the Army. That was rea not quite the position. In these estimates out of a to of £41,000,000, £2,400,000 was being devoted to the medi services. Unfortunately it was true that they had not t number of doctors who were required for their establi ment. They had done their best to make the Serv attractive. He had conferred with his medical advis and with the medical societies, and he thought now at a rate the terms and conditions of service were agreeable the medical profession. He had had the endorsement the medical profession. The short service which had b referred to he brought in two years ago. Men could n join for seven years, and if they then wished to retire was optional—they had a gratuity of £1000. Of course hon. friend wanted more. He wished he could give Service more, but let him not say £1000 was nothing. was a very useful addition to the capital of a young medi man who was about to set up in practice. As to the gri ance that the Army Medical Service were not direc represented on the Army Council, every branch of Service could not be directly represented on the Ar Council when there were only four military members the Council. But the Director-General of Medical Servi had direct access to the Secretary of State at any t without having to go through any military superior.

The motion to reduce the vote was rejected by 189 v to 20.

HOUSE OF COMMONS.

THURSDAY, MARCH 8TH.

Lunacy Administration.

Mr. FREDERICK ROBERTS asked the Minister of He what amount had been expended on lunacy administra in the last year for which statistics were available; many certifications took place during the same peri and how many people were discharged.—Mr. CHAMBERL replied: The expenditure of local authorities in Engl and Wales on lunacy administration for the financial y 1926–27 amounted to £7,803,804. During the same pe loans were sanctioned for capital expenditure amountin £242,335. During the calendar year 1927 the certificat and discharges were as follows:—

	Certifications.	Discharg
Public mental hospitals ..	20,474	9,823
Other institutions and single care	1,419	892
Total	21,893	10,71

Anthrax Statistics.

Dr. VERNON DAVIES asked the Home Secretary number of cases of anthrax in this country for the last t years for which statistics were available and the origi infection in each case.—Sir WILLIAM JOYNSON-H replied: I can give only the figures for cases of anth reported in factories and other premises under the Fac and Workshop Acts in the years 1925 to 1927. The p cipal figures in the table give the number of cases; figures in parentheses give the number of deaths.

Origin of infection.	1925.	1926.	1927.	Tot
Wool and hair (other than horsehair) ..	26 (5)	16 (2)	18 (1)	60
Horsehair or bristles ..	3 (2)	8 (1)	3 (1)	14
Hides and skins ..	18 (3)	15 (1)	13 (1)	46
Other*	1	3	1	5
Total	48 (10)	42 (4)	35 (3)	125

* The suspected materials in these cases were: feather bones, 1; felt or tanned leather, 1; refuse from an products, 1; not ascertained, 1; total, 5.

Factory Inspection in Scotland.

Mr. BUCHANAN asked the Home Secretary if he was aware hat in a large number of factories situated in the West of cotland particularly employing young female labour actory inspectors rarely, if ever, paid a visit; and what eps he was prepared to take to secure safety by having roper inspection made.—Sir W. JOYNSON-HICKS replied: he hon. Member exaggerates the position. I am informed hat out of 157 factories in the West of Scotland employing oung girls which were not inspected last year, 86 had been isited within a period of 15 months, and all but six of them ithin two years. I have repeatedly stated that I am not atisfied with the present strength of the factory inspectorate, nd that I propose to set up a committee to examine the uestion. As the committee would have to take account the new situation created by the Factories Bill, I had ot contemplated appointing it until the Bill had been assed. I am very anxious, however, particularly as the ill has been postponed till next year, that no time should e lost, and I am proposing to advance the commencement this inquiry and proceed with the appointment of the mmittee in the autumn.

Importation of Dangerous Drugs.

Mr. DAY asked the Home Secretary whether his attention ad been called to the remarks of the coroner at a Kenngton inquest on Mrs. Ida Mary Gropper, in which he ated that he was strongly of the opinion that legislation ould be introduced for the purpose of restricting the nport of the French hypnotic drug known as dial; and hether he proposed to take any action in the matter.—r WILLIAM JOYNSON-HICKS replied: Yes, Sir. The uestion of the need for further restrictions in the case of rtain kinds of drugs has been brought before the Interpartmental Committee which has been examining the w relating to poisons. I will see that the circumstances the case to which the question refers are brought to the tention of the Committee.

MONDAY, MARCH 12TH.

Royal Air Force Hospitals.

Dr. VERNON DAVIES asked the Secretary of State for Air he would give a full list of Royal Air Force hospitals at me and abroad, the number of beds in each hospital, id the personnel attached to each hospital.—Sir S. HOARE plied: The following is the information requested:—

Locality of the R.A.F. hospitals.	Equipped beds.	Hospital personnel.		
		Officers.	Nurses.	Airmen.
ome—				
Halton	309	9	38	98
Cranwell	100	6	12	41
Uxbridge	31	4	9	10
aq—				
Hinaidi	200	10	23	75
Basrah	35	5	7	24
alestine—				
Sarafand	77	5	6	35

This statement is based on the present establishment, hich is now under review. It should be added, first, at the hospitals in Iraq and Palestine provide for British my officers serving with the local ground forces in these untries, and for certain British civil officials in addition the Royal Air Force; and, secondly, that the personnel tached to most of them also perform duties apart from e duties directly connected with the respective hospitals—g., the officers at the Cranwell Hospital are also medical icers for the Cranwell Command as a whole. The Indian ctions of the hospitals in Iraq are excluded.

Experiments on Living Animals.

Mr. NEIL MACLEAN asked the Home Secretary whether had caused any inquiry to be made as to the large increase the number of experiments performed on living animals d, if so, whether any reason had been given for such an crease; and, if no inquiry had been made by his depart-nt, whether he would institute one.—Sir WILLIAM YNSON-HICKS replied: The increase referred to is mainly inoculations, feeding experiments, and similar procdures; and I understand that it is due principally to the velopment of medical science in regard to the standardising drugs and the investigation of vitamins, and to the steps ken to safeguard the purity of the milk-supply. I see no ound for any special inquiry.

TUESDAY, MARCH 13TH.

Temporary Commissions in the R.A.M.C.

Mr. BARNES asked the Secretary of State for War whether -Service men were disqualified for appointment to a temporary commission in the Royal Army Medical Corps if they were in receipt of a disability award.—Sir L. WORTHINGTON-EVANS replied: The fact that an ex-Service man is in receipt of a disability award is not in itself a disqualification for appointment to a temporary commission in the Royal Army Medical Corps, but such cases have naturally to be considered very carefully in view both of the possibility of aggravating the disability and of the danger of the officer's breakdown in the performance of his duties.

Pension Awards.

Mr. WALTER BAKER asked the Minister of Pensions the number of first awards of pension to fresh applicants during 1927, and the number of conditional awards current on Jan. 1st, 1928.—Lieut.-Colonel G. F. STANLEY (Parliamentary Secretary to the Ministry of Pensions) replied: The total number of first awards of all kinds made in the calendar year 1927 was 4355. On Jan. 1st, 1928, there were about 8500 officers and nurses and 146,000 men in receipt of conditional awards in respect of disablement arising out of service in the Great War.

Treatment of Scottish Disabled Pensioners.

Dr. SHIELS asked the Minister of Pensions (1) how many disabled pensioners there were in Scotland, and what was the average number for the last three years of disabled or affected men without pension who had attended the Ministry centres for treatment; (2) how many men in Scotland last year received home treatment with allowances, and what was the total number of hospital beds in Scotland which the Ministry considers adequate; and (3) how many Scottish disabled men were being treated in England; what were the numbers for the respective diseases or conditions; and where were the places of treatment.—Lieut.-Colonel G. F. STANLEY replied: The total number of disabled officers, nurses, and men in receipt of pension or other grant from the Ministry in Scotland is approximately 43,000. The average number of patients attending at Ministry clinics in Scotland and in receipt of in-patient treatment in each of the last three years was as follows:—

	Clinics.	Ministry Hospitals.
1925	960	.. 600
1926	610	.. 495
1927	425	.. 365

1484 disabled men received treatment at home together with allowances during the year 1927. The Ministry has in view hospital accommodation in Scotland for current needs of about 400 beds, which will provide a substantial reserve. In view of the decline in the requirements of hospital treatment, I am unable to estimate what accommodation may ultimately be found to be necessary; 105 Scottish disabled men are under treatment in Ministry hospitals in England. Of these 99 are in four hospitals—viz., Harrowby, Orpington, Cosham, and Maghull—which have been established for the treatment of special forms and degrees of nervous disease, including epilepsy, and six are medical and surgical cases receiving special treatment in Mossley Hill (1), Sidcup (2), and Roehampton (3) hospitals.

Use of Emulsifiers in Cream.

Mr. LAMB asked the Minister of Health (1) whether his attention had been drawn to the increasing use of emulsifiers for the reconstitution of cream as a result of the enforcement of the Public Health (Preservatives, &c., in Food) Regulations; how many prosecutions had taken place in cases of the fraudulent sale of the synthetic article as cream; and what further steps, if any, were contemplated by his department with a view to the suppression of the practice; and (2) whether he regarded synthetic cream as a foodstuff for the purposes of the Public Health (Preservatives, &c., in Food) Regulations; and what steps, if any, had been taken by his department to deal with the sale, as cream, of the synthetic article containing preservative.—Sir KINGSLEY WOOD replied: My right hon. friend's attention has been drawn to the increasing use of emulsifiers for the reconstitution of cream, but it does not seem likely that the Preservatives Regulations are responsible for the increase. I would point out that the prohibition of preservatives applies equally to natural and to reconstituted cream. A more probable explanation can be found in the fact that the latter article is said to be prepared at a cost much lower than that of the former. I am unable to state how many prosecutions have been instituted by the local authorities in respect of the sale of the synthetic article as cream. As my hon. friend is probably aware, the constituents of cream can be emulsified so as to produce an article which is very similar to natural cream. Investigations are, however, being made as to the possibility of distinguishing between the two articles by scientific methods. Pending the completion of these investigations, I am not in a position to indicate what further steps can be taken by my department

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At a meeting of the College held on March 8th the diploma of Fellow was conferred on Joseph T. Fathi (London Hospital).

Diplomas in Tropical Medicine and Hygiene were conferred (jointly with the Royal College of Physicians) upon the following candidates, who have studied for the diploma at the London School of Hygiene and Tropical Medicine :—

C. R. Amies, Mary N. Andrews, R. E. Barrett, A. Bearblock, S. Bergsma, A. Dunlop, H. Fairbairn, Elisabeth Farra, H. A. Fawcett, M. M. Fihri, O. M. Francis, W. E. Giblin, H. K. Giffen, H. H. Gilbert, J. C. P. Grey, Alma B. Harvey, Eva Ho Tung, W. A. M. Jack, D. R. Jandial, B. M. Johns, R. S. Johnston, E. B. Jones, Margaret E. Lovett, Margaret M. McDowall, A. A. M. Magraby, R. C. Mahajan, M. V. Merchant, J. C. Milne, J. H. Oonvala, Thaliakattu Parukutti Ammal, J. R. Pierre, E. W. Reece, J. D. Reynolds, Enid A. Robertson, G. I. Shaw, T. A. Sherwin, G. A. Sloan, Hilda M. Smith, A. E. M. Soliman, Grace M. L. Summerhayes, V. E. Whitman, N. J. Willans, C. H. Williams, H. M. Willoughby.

Licences in Dental Surgery were conferred upon the undermentioned candidates :—

W. J. M. Allan and B. Cohen, Guy's; N. L. Craddock and G. S. Cubitt, Royal Dental; A. H. Curtis, Guy's; R. D. Daly, London; Cicely M. Finnemore, Royal Dental; R. P. Graham, Birmingham; L. E. James, Guy's; C. L. Noble, London; V. R. Preen, Guy's; W. I. Robertson, King's Coll.; L. R. Rowlands; M. A. Rushton, and C. J. C. Siggers, Guy's; E. Slack, Manchester; C. L. Stevens, Guy's; F. W. Threlfall, Univ. Coll.; H. C. J. Van den Brocque, Guy's; and J. Winter, Royal Dental.

UNIVERSITY OF LONDON.—Prof. Robert Robinson, F.R.S., has been appointed as from August 1st, 1928, to the University Chair of Organic Chemistry, tenable at University College.—Dr. J. B. Christopherson has been appointed examiner in tropical medicine for the year 1928 in place of the late Sir Percy Bassett-Smith.—Sir Wilmot Herringham has resigned his Membership of the Senate as one of the representatives of the Royal College of Physicians of London. In view of the forthcoming reconstitution of the University, the College does not propose to fill the vacancy.

The ceremony of Presentation Day will this year be held at the Albert Hall on Wednesday, May 9th, at 3 P.M. A Graduation Dinner will be held on the same day at 8 P.M. at the Grocers' Hall, Princess-street, E.C. Requests for tickets may be made to Mr. V. E. Wall, University of London, South Kensington, S.W. 7.

Applications for the University Chair of Biochemistry, tenable at the London School of Hygiene and Tropical Medicine, must be made in proper form to the Academic Registrar not later than April 11th.—A Carpenter medal, together with a money prize, will be awarded in 1928 for a thesis in statistical, genetic, comparative or experimental psychology, including the functions of the central nervous system and special senses, for which a doctor's degree other than Ph.D. degree has been awarded within three years ending May 31st, 1928.—The Senate will shortly consider grants from the Dixon Fund, which are allotted annually to assist scientific investigation. Grants will also be made from the Thomas Smythe Hughes Medical Research Fund, whilst applications are invited for the Laura De Saliceto studentship for the advancement of cancer research of the value of £150 a year. Particulars of these funds may be had from the Academic Registrar.

The election of Beit Fellows will take place on or about July 16th. Candidates must be under the age of 25, and not more than three Fellowships, of the annual value of £250, will be awarded. Applications must be received before April 20th on forms to be obtained by letter only from the Rector, Imperial College, South Kensington, S.W. 7.

At its meeting on Feb. 22nd the Senate approved a number of amendments to the regulations for the Diploma of Nursing.

THE LONDON HOSPITAL: QUINQUENNIAL APPEAL.—At the quarterly meeting of the House Committee, Lord Knutsford, the chairman, stated that his quinquennial appeal had, so far, produced a little over £44,000, £20,000 of which was the result of his broadcast appeal. During the past year there was a slight decrease in the number of patients treated; the average residence of the 16,000 in-patients was 15 days. The patients admitted contributed £32,075, an increase of £3368, chiefly due to the spread of the Hospital Saving Association.

ROYAL INSTITUTION.—On Thursday, March 22n at 5.15 P.M., Group-Captain Martin Flack will give t first of two lectures on Physiological Aspects of Flying.

BRITISH ORTHOPÆDIC ASSOCIATION.—The Robe Jones Medal and Association Prize for 1927 has been award to Mr. J. F. Brailsford for an essay on Deformities of t Lumbo-sacral Region of the Spine.

ST. ANDREW'S HOSPITAL, DOLLIS HILL.—T annual report shows that during the year there was average of 58 patients daily in residence in the hospit which is intended for the professional and middle class As there are only 52 regular beds, emergency accommodati had to be supplied. The hospital is trying to raise £15,0 at once towards the £30,000 required for a new buildi which will include a children's ward.

FELLOWSHIP OF MEDICINE AND POST-GRADUA MEDICAL ASSOCIATION.—On Monday, March 19th, 5 P.M., Prof. F. Langmead will deliver a lecture at t Medical Society of London, 11, Chandos-street, Cavendi square, on Dull and Backward Children. On Thursd March 22nd, at 5 P.M., Prof. Louise McIlroy will give lecture-demonstration at the Royal Free Hospital, and the same date, at 6.30 P.M., Mr. Theodore Just will give demonstration at the Golden-square Throat Hospit The lecture and demonstrations are open to members the medical profession without fee. From March 19 for a week, an intensive course will be given at the Hospi for Consumption and Diseases of the Chest, Brompto and from the same date for a fortnight, an all-day cou will be given at the Royal National Orthopædic H pital. A course for the general practitioner will be giv from the same date to March 30th at the Hampstead Gene Hospital, from 4.30 to 6 P.M., the instruction including demonstration or lecturette in medicine, surgery, and t specialties. No special courses will take place betwe March 31st and April 16th owing to the Easter Holida Information, syllabuses of special and general cours tickets, and copies of the *Post-Graduate Medical Journ* may be had from the Secretary of the Fellowship, 1, Wimpole-street, London, W.

HEALTH AND CLEANLINESS COUNCIL.—On March 9 the Council held its annual meeting at the Hotel Ce The proceedings, which dealt with the aims of the Coun and the extension of its work of assisting health activit by providing books, pamphlets, posters, lecturers, a cinematograph films, were held in private between lun and tea, after which were shown some of the films whi the Council lends without charge to bodies with simi objects. Dr. Andrew Balfour, proposing the health of t Council at lunch, said that the old Scots saying, "T clartier the cosier," had been changed by the pioneer pub health work of this country to "The dirtier the deadlie and that a man who lived under dirty conditions was danger not only to himself but to others. Fortunately t truth of that axiom was more apparent in tropical countr nowadays than in our own, but if anyone should think th all was well in England he had only to look at the state some London streets. It was, he said, a little beyond joke when foreign students at his school came and sai "You are always telling us about the necessity for cleanlin in the tropics; England is the cradle of hygiene; will y come out and look at some of the back streets here and s how they are?" Another possible field for the Counci activities was the sanitary provision for workmen engag on the many new buildings that were being erected in t city; until representations had been made the sanitati in the new School of Tropical Medicine itself would have l much to be desired. Americans who came to this count interested in hygiene matters were shocked at the way which our food was handled. In spite of numerous co mittees and reports, food was exposed where it should n be exposed. Fortunately there were not many flies, there would be a worse tale to tell. Dirt led not only danger, but to a lowering of the moral tone, and he look to the Council to combat the tendency towards decaden in these matters. On the bright side Dr. Balfour quot from an article in the *Journal of the American Medi Association* on typhoid in some of the largest Europe cities. No other country but this, he read, could show long a list of large cities free from a single typhoid deat and our freedom from this disease was a fine testimony the work of the public health service in this country. T new activities of the service, such as those against tub culosis and venereal disease, should not be allowed to pu cleanliness into the background, and it was fortunate th a Council such as this existed to guide the people up proper lines. Dr. G. F. Buchan, the President, outlin the objects of the Council, and each member of the par received a sample of its educational books, a work entitl Health and Cleanliness, a Text-book for Teachers.

ST. MARK'S HOSPITAL.—At the annual meeting on March 8th the Lord Mayor of London announced that the number of beds at this hospital had been increased to 72, and that an up-to-date cancer research laboratory had been provided. Last year 583 patients were admitted to the wards, and 6440 out-patients attended.

UNIVERSITY OF HONG-KONG.—At a congregation held on Jan. 9th the degree of M.D. was conferred on D. K. Pillai, and the degrees of M.B., B.S. upon 17 candidates. Under the Medical Act, 1886, degrees conferred by this University are registrable in the Colonial List of the Medical Register.

OXFORD OPHTHALMOLOGICAL CONGRESS. — The eighteenth annual meeting of this Congress will be held at Keble College from July 4th to 7th. On July 5th there will be a symposium on the Ultra-violet Ray, introduced by Dr. Leonard Hill, F.R.S., followed by Mr. W. S. Duke-Elder, and others. The Doyne Memorial Lecture will be delivered on July 6th by Prof. Arthur Thomson, his subject being Observations on the Eyes of Birds. Further information may be had from the Hon. Secretary, Mr. Bernard Pridland, Salisbury House, Wolverhampton.

NEUROLOGY AND PSYCHIATRY: COURSES AT VIENNA.—Systematic post-graduate classes in neurology and psychiatry will be held in English at the Neuropsychiatric Clinic of Prof. Wagner-Jauregg and the Neurological Institute of Prof. Marburg at Vienna University under the auspices of the American Medical Association of Vienna, from June 1st to July 31st. The fee will be $214 and the class will consist of not less than 8 and not more than 15 members. Further information may be had from Docent Dr. E. Spiegel, Vienna, I., Falkestrasse 3.

KING EDWARD'S HOSPITAL FUND FOR LONDON.—We are informed that hospitals situated within 11 miles of St. Paul's desiring to participate in the grants made by the Fund for 1928 must apply before March 31st to the hon. secretaries of the Fund at 7, Walbrook, E.C. 4 (G.P.O. Box. 465A). Applications will also be considered from convalescent homes which are situated within the above area which take a large proportion of patients from London.

JEWISH HOSPITAL FOR LIVERPOOL.—Negotiations between the Liverpool Jewish Hospital Committee and the existing hospitals for the setting aside of two wards for Jewish patients have failed. It has therefore been decided to found an independent establishment, it having been decided that the setting aside of two wards, with the supply of special food, would be practically as expensive as a separate institution. The new hospital will have 20 beds and a kosher kitchen. An offer to defray the costs has already been received.

BRITISH MEDICAL ASSOCIATION: SCHOLARSHIPS AND GRANTS IN AID OF SCIENTIFIC RESEARCH.—The Council of the B.M.A. will receive applications as follows:—

Research Scholarships.—An Ernest Hart Memorial Scholarship of £200 per annum, and three other research scholarships of £150 per annum are offered to candidates undertaking research in any subject (including State medicine) relating to the causation, prevention or treatment of disease. Each is tenable for one year, commencing on Oct. 1st, 1928. A scholar may be reappointed for not more than two additional terms, may hold a junior appointment at a university, medical school, or hospital, provided its duties do not interfere with his work as a scholar.

Grants.—The Council will also receive applications for grants for the assistance of research in the same directions, preference being given to applicants who propose to investigate problems directly related to practical medicine.

Applications for scholarships and grants should be made on the prescribed form (to be had from the Medical Secretary, B.M.A. House, Tavistock-square, London, W.C. 1) before June 2nd.

THE LANCET: SUBSCRIPTION RATES.

INLAND	One Year	£2	2	0
	Six Months	1	1	0
	Three Months	0	10	6
ABROAD	One Year	2	10	0
	Six Months	1	5	0
	Three Months	0	12	6

Subscriptions not paid in advance are charged out at the published price of 1s. per copy, plus postage. Cheques and P.O.'s (crossed "Westminster Bank, Ltd., Covent Garden Branch") should be made payable to THE MANAGER. THE LANCET Offices, 423, Strand, London, W.C. 2.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, March 20th.—5.30 P.M., SPECIAL GENERAL MEETING OF FELLOWS. 8.30 P.M., PATHOLOGY. Election of Officers and Council. Communications: Cuthbert Dukes: Some Observations on Pyuria. S. P. Bedson and J. Bland: Cross Immunity Between Vaccinia and Herpes Virus. J. H. Orr and W. A. Campbell: The Action of Welchii Toxin on Red Cells in Vitro. Demonstrations: R. W. Scarff: Carcino-sarcoma of Œsophagus. Myelin Kidney.

THURSDAY.—8.30 P.M., UROLOGY. Discussion on the Treatment of Stricture by Excision. Opener: Mr. Frank Kidd.

FRIDAY.—5 P.M., DISEASE IN CHILDREN. (Cases at 4.30 P.M.) Cases will be shown. 8 P.M., EPIDEMIOLOGY Paper: Dr. C. O. Stallybrass: Season and Disease.

CHELSEA CLINICAL SOCIETY.

TUESDAY, March 20th.—8.30 P.M. (at the Hotel Rembrandt, Thurloe-place, S.W.), Dr. H. Fielden Briggs and Dr. A. Livingstone will open a discussion on Modern Aspects of Dentistry. The meeting will be preceded by dinner at 7.30 P.M.

MEDICO-LEGAL SOCIETY.

THURSDAY, March 22nd.—8.30 P.M. (at 11, Chandos-street, Cavendish-square, W.), Dr. Gerald Slot: Pain in its Medico-legal Aspects, followed by a discussion.

HUNTERIAN SOCIETY.

MONDAY, March 19th.—8.30 P.M.; Dinner at 7.30 P.M. (at Simpson's Restaurant, Bird-in-Hand-court, 77, Poultry, Cheapside), Discussion on Hiccup, to be opened by Dr. R. Hutchison and Sir Farquhar Buzzard.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

THURSDAY, March 22nd.—5 P.M., Dr. J. S. Collier: Epilepsy. (Lumleian Lecture (1).)

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

FRIDAY, March 23rd.—5 P.M., Prof. Sir Arthur Keith: A Review of the Present State of Knowledge Regarding the Innervation and Movements of the Intestine.

ROYAL INSTITUTION, 21, Albemarle-street, W.

THURSDAY, March 22nd.—5.15 P.M., Group-Captain Martin Flack: Physiological Aspects of Flying.

SOUTH-WEST LONDON POST-GRADUATE ASSOCIATION, St. James's Hospital, Ouseley-road, Balham, S.W.

WEDNESDAY, March 21st.—4 P.M. (at the Battersea Mortuary), Sir Bernard Spilsbury: Post-mortem Examination.

NATIONAL HOSPITAL, Queen-square, Bloomsbury.

MONDAY, March 19th.—2 P.M., Dr. Hinds Howell: Out-patient Clinic. 3.30 P.M., Dr. Kinnier Wilson: The Narcolepsies.

TUESDAY, 2 P.M., Dr. Walshe: Out-patient Clinic. 3.30 P.M., Dr. Hinds Howell: Disorders of Sensation (2).

THURSDAY.—2 P.M., Dr. Kinnier Wilson: Out-patient Clinic. 3.30 P.M., Dr. Bailey: Treatment of Pain by Electrical Methods.

FRIDAY.—2 P.M., Dr. Adie: Out-patient Clinic. 3.30 P.M., Sir Percy Sargent: Surgery of the Spinal Cord.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 19th, to SATURDAY, March 24th.—FELLOWSHIP OF MEDICINE LECTURE, Medical Society of London, 11, Chandos-street, Cavendish-square, W. Mon., 5 P.M., Prof. Frederick Langmead: Dull and Backward Children.—HOSPITAL FOR DISEASES OF THE THROAT, Golden-square, W. Thurs., 6.30 P.M., Special Clinical Demonstration by Mr. Theodore Just.—ROYAL FREE HOSPITAL, Gray's Inn-road. Thurs., 5 P.M., Special Lecture-demonstration by Prof. Louise McIlroy.—BROMPTON HOSPITAL, S.W. Intensive Course for one week.—HAMPSTEAD GENERAL HOSPITAL, Haverstock Hill, N.W. Practitioner's Course in Medicine, in Surgery, and in the Specialties. Mon. to Fri., 4.30 to 6 P.M.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, 234, Great Portland-street, W. All-day Course—Clinics, Operations, Lectures.

Further particulars from the Secretary. Mayfair 2236.

HOSPITAL FOR SICK CHILDREN, Great Ormond-st., W.C.

THURSDAY, March 22nd.—4 P.M., Dr. B. Shires: X Ray Diagnosis; Diseases of the Chest.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith.

MONDAY, March 19th.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Dr. Trevor Davies: Gynæcological Department. 4.30 P.M., Mr. Addison (Special Lecture): Gastric Ulcer.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose, and Ear Department. 4.30 P.M., Dr. Shaw (Special Lecture): Chest Pain.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 3 P.M., Sir Henry Simson: Gynæcological Ward.

FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon, Dr. Ironside: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.

Daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M., In-patients, Out-patients, Operations, Special Departments, Anæsthetic and Operative Surgery Classes.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, March 19th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose, and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Wednesday and Friday, at 2.30 P.M., there will also be demonstrations of Skin and Medical (Children) Cases by Dr. W. Jenkins Oliver and Dr. C. E. Sundell respectively.

On Monday and Friday there will also be demonstrations of Surgical and Medical Cases by Mr. Ralph Coyte and Dr. L. R. Yealland respectively.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, March 20th.—5 P.M., Dr. H. MacCormac: Malignant Growths of the Skin.

THURSDAY.—5 P.M., Dr. H. G. Adamson: Benign Growths of the Skin.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, March 23rd.—4 P.M., Mr. Watkyn-Thomas: The Indications for the Radical Mastoid Operation.

ST. PAUL'S HOSPITAL, Endell-street, W.C.

THURSDAY, March 22nd.—4.30 P.M., Sir Thomas Carey Evans: Stone in the Bladder, with Special Reference to Treatment by Letholapaxy.

PEOPLE'S LEAGUE OF HEALTH.

FRIDAY, March 23rd.—6 P.M. (at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, W.), Dr. Bassett Jones: Diet in Rheumatic Diseases.

ANCOATS HOSPITAL POST-GRADUATE LECTURES, Mill-street, Manchester.

THURSDAY, March 22nd.—4.15 P.M., Mr. P. G. McEvedy: Visceroptosis.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, March 20th.—4.15 P.M., Mr. C. Roberts: Treatment of Enlarged Prostate.

FRIDAY.—4.15 P.M., Dr. C. H. Melland: Demonstration of Medical Cases.

Appointments.

FOX, I. S., M.B., Ch.B. Liverp., to be Certifying Surgeon under the Factory and Workshop Acts for the Chester District.

Vacancies.

For further information refer to the advertisement columns.

Artificial Sunlight Clinic, 43, Leicester-square, W.C.—Hon. M.O.

Ashton-under-Lyne District Infirmary.—Third H.S. At rate of £150.

Aylesford, Kent, Hospital, &c., for Tuberculous Ex-Service Men Jun. P. £100.

Barbados Lunatic Asylum.—Asst. Med. Supt. £500.

Cambridge, Addenbrooke's Hospital.—H.S. At rate of £139.

Charing Cross Hospital.—Surg. Reg. £150. Also Asst. Surg

City of London Hospital for Diseases of Heart and Lungs, Victo Park, E.—P. to Out-patients.

Dublin, City Skin and Cancer Hospital.—Res. H.S., &c.

Dumfries, Crichton Royal Mental Hospital.—Clin. Patholog £400.

East London Hospital for Children and Dispensary for Wom Shadwell, E.—Asst. S.

Evelina Hospital, Southwark, S.E.—Med. Radiographer. £1 Also H.S. £120.

Hereford County and City Mental Hospital.—2nd A.M.O. £3

Hong-Kong.—Two Asst. M.O.H.'s Each £740.

Hospital for Sick Children, Great Ormond-street, W.C. 1.—H. H.P., and Asst. Cas. O. Each £50.

Huddersfield County Borough.—Asst. M.O.H. £500.

Indian Medical Service.—Commissions.

Ipswich, East Suffolk and Ipswich Hospital.—H.P. and H. Each at rate of £100.

King Edward Memorial Hospital, Ealing, W.—Res. Asst. H At rate of £100.

Liverpool Heart Hospital.—Hon. Asst. Phys.

Manchester, Victoria Memorial Jewish Hospital.—Sen. H £250.

Middlesex Hospital Medical School, W.—Scholarship in Chem Pathology. £150.

Miller General Hospital for South-East London, Greenwich-r S.E.—Hon. P. to Children's Spec. Dept.

Northampton General Hospital.—Asst. H.S. At rate of £15

Norwich, Norfolk and Norwich Hospital.—Hon. Surg. for I Nose and Throat Dept.

Nottingham General Dispensary.—Res. Lady Surg. £250.

Plymouth, South Devon and East Cornwall Hospital.—H.S., H and Cas. H.S. All at rate of £50.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s H.P., also Jun. H.S. and Jun. H.P. At rate of £120 and respectively.

Queen's Hospital for Children, Hackney-road, E.—P. in charg Skin Dept.

Rochdale Infirmary and Dispensary.—Jun. H.S. £200.

Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. Also Res. Anæsthetist.

Shanghai Municipal Council.—Second Asst. Commissione Public Health. Taels 600 per mensem.

South London Hospital for Women, Clapham Common, S.W. H.P. and H.S's. Each at rate of £50.

Sutton, Surrey, Downs Hospital for Children.—Jun. Asst. M £500.

West London Hospital, Hammersmith, W.—Hon. Med. I £100. Also Hon. Anæsthetist.

Willesden General Hospital, Harlesden-road, N.W.—Res. At rate of £100.

Births, Marriages, and Death

BIRTHS.

GLINDON.—On March 5th, at Stoneleigh, Wimbledon, the of Reginald A. Glindon, L.D.S. R.C.S. Eng., of a daugh

HIGGINS.—On March 6th, at "Ringrone," Woking, Surrey, wife of Dr. L. G. Higgins, of a son.

MARRIAGES.

GREY—WILLIAMS.—On Feb. 29th, at St. Mark's, Little Comm Bexhill, John C. P. Grey, M.A., M.B., to Ella Ida second daughter of the late Mr. G. E. Williams, of E Duars, Bengal, India, and of Mrs. G. E. Williams Cooden, Bexhill.

DEATHS.

BROWNE.—On March 7th, Henry William Langley Brow O.B.E., LL.D., M.D., F.R.C.S.E., J.P., at 196, Hagley-r Edgbaston, aged 79.

FERGUSON.—On March 5th, at a nursing home, Edinbu William Haig Ferguson, M.C., M.A. Camb., M.B., Capt R.A.M.C., aged 37.

PASSMORE.—On March 7th, suddenly, of heart failure follow pneumonia, J. Ernest Passmore, M.R.C.S., L.R.C.P. Doddington, March, Cambs, aged 61.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notice Births, Marriages, and Deaths.

FATAL STREET ACCIDENTS IN LONDON.—Scotl Yard has just published, for the first time, details of causes of fatal street accidents in London. The ret which covers the last quarter of 1927, shows that mos the accidents happened to adults, and that children tau "safety first" in schools are so careful in crossing the str that they avoid accidents. In the three months 312 per were killed, only 55 of whom were under 15 years of

Notes, Comments, and Abstracts.

PARALYSIS CURED BY MALARIA.

THE FIRST KNOWN CASE—1850.

By E. W. GUDGER,

BIBLIOGRAPHER AND ASSOCIATE IN ICHTHYOLOGY, AMERICAN MUSEUM OF NATURAL HISTORY, NEW YORK CITY.

DURING the past eight or ten years much interest has been aroused in the malarial treatment of paralysis, and the medical literature abounds in reports of cases where paralytics have been subjected to bites by mosquitoes bearing malarial germs or have been directly infected hypodermically with *Plasmodium malariæ*. The malarial attacks relieve the paralysis and the germs are then destroyed by the use of quinine. Of late rat-bite fever has also been found efficacious, its germs being killed by arsphenamine when their work is done.

I am not a medical man, and have no first-hand knowledge of these matters. Some months ago, however, while checking up the medical bibliographies in search of articles on fishes therein contained, I chanced upon an account of such a phenomenon which was reported 76 years ago. Since this is of great historical interest to medical men, I am reproducing the report herein in the exact form in which it was originally published in the *New Orleans Medical and Surgical Journal* (1850, vii., 41). It is entitled "A Case of Hemiplegia (Cured by an Attack of Fever)," by A. Morris, M.D., of Lowndes County, Ala.

"February, 1848—Enoch Singleton, (64)—Attacked with hemiplegia: the only treatment for the first few days, as far as I could ascertain, was mild laxatives and strychnine. I saw him for the first time ten days after the attack: entire loss of motion on one side of the face; but very little use of either extremity of same side; considerable pain in the occipital, extending front, below the ear of side affected: cups to the nape of the neck; blister to the same region, continue use of the strychnine. Treatment continued for a few days. No improvement. Ordered all medicines stopped, and use cold bath once a day. Improved slowly; able to get about tolerably; face worse; sensation and motion both gone. Continued about the same until August 5th; had a chill; took a small dose of calomel on the 7th; drank very freely of pepper tea, in hopes to keep both disease and chill off. I was called in on evening of same day; found him with much fever, and pulse quick, soft, and intermitting; skin hot and dry; tenderness over the abdomen generally; pain in head; delirium.

℞ Sub. Hyd. x. gr.;
Pulv. Dov. gr. xv. M. No. vi.;

one every two hours until fever subsides, or all are taken; mustard poultice to abdomen; left twenty grains quinine in five powders, to be taken one every four hours; to commence as soon as skin becomes moist.

"Morning of the 8th, 10 o'clock.—No fever; pulse seventy—full and soft; skin moist; hiccough; complains of pain in head; bowels have moved twice; taken all the quinine.

℞ Sulph. Morph. 1–4 gr. immediately.
℞ Gum Assafœtida.
Quinine āā. x. gr. M.

in pill No. vi, one every three hours.

℞ Sulph. Morph. 1 gr. et divid.

in four powders—one every four hours till hiccough ceases.

"9th.—Much worse; hiccough constant; great prostration; pulse soft; no pain; blister two by eight over diaphragm; one, two by six to spine; cups; internally camphor, must and assafœtida.

"10th.—Prostration complete; no pulse at wrist; breathing laborious; hiccough constant; blister drew well; brandy and quinine freely—can't say what amount; camphor poultice to abdomen; spent the day with him; no change until six in the evening; pulse to be felt occasionally; at midnight distinct; skin moist; hiccough continues; 1–4 gr. morphine repeated every half hour.

"Morning of 11th.—Hiccough less frequent; health better; slept about an hour for the first time; quinine and assafœtida 1–2 grains each every three hours; blue pill and aloes āā v. grs.

"12th.—Much better; pulse tolerably full; hiccough continues, but at intervals; recognises me, but unable to articulate; bowels moved twice; gums sore; has been frequently ptyalised before; continue quinine and assafœtida; took a little gruel.

"13th.—Has slept considerably; hiccough continues, but at intervals of an hour or more. From this time took nothing but quinine and assafœtida; improved regularly on, until finally discharged on the 19th, well both of the present attack and the paraplegia—not a vestige remaining: face straight, and in fact all correct; in better health from this time until Nov. 18th, 1849, than for years previous. At the above date he called on me to show a sore arm of some few days' standing; upon examination found he had phlebitis of the left arm; it was much swollen; painful, stiff, and red, in the course of the vein from the shoulder to near the hand; the vein felt like a cord, and full of knots—size of filberts; complains of cold chills running over him constantly for the last twelve hours; constitutional symptoms very trifling, but slight acceleration of pulse; no fever.

℞ 24 grs. calom., vi. grs. opii. M.
Divide in pulv. No. xii.;

one three times a day; keep quiet; use poultices; whiskey and water, or water, as may feel best to arm. Saw him a few days after; three of the knots had gone on to ulceration; opened spontaneously; looked very much like common boils. He is now well."

NATIONAL BABY WEEK COUNCIL.

THE annual general meeting of the Council was held at Carnegie House on March 7th, Mr. E. B. Turner presiding. The Astor Challenge Shield for the great towns (won by Northampton), the William Hardy Challenge Shield for smaller areas (won by Cambridgeshire villages), and other awards for the most successful baby week campaign were presented. After adoption of the report and appointment of honorary officers an address on the Prevention of Maternal Mortality was given by Prof. Louise McIlroy. She referred to two measures which would help in bringing down the maternal death-rate—viz., to extend throughout the country the standard of efficiency in obstetrics now maintained in the voluntary hospitals, and to ensure that every pregnant woman should be examined at least once during the antenatal period. The health of the woman after confinement was as important as the prevention of deaths due to childbirth. Vesico-vaginal fistula, which used to be common, was now so rare that she had not seen a case in the last seven years of constant maternity work. Diminution in prolapse and other disabling postnatal conditions was further evidence of the better conduct of labour. Cases in which pregnancy was complicated by heart disease were now discovered early, owing to antenatal care, and there had been no death during labour or the puerperium among 150 cases with heart complications treated at the Royal Free Hospital. The three essentials in combating a high maternal mortality-rate were, said Prof. McIlroy, these: (1) modern maternity institutions, with special accommodation for antenatal care; (2) proper housing conditions when confinements were to be conducted in the home, with skilled attention from doctor and nurse, and transport facilities when necessary; (3) examination by a doctor of every mother at least once during pregnancy, and once after convalescence in cases where the confinement had been attended by a midwife.

LEAD POISONING FROM SNUFF.

CERTAIN sources of lead poisoning by food are well recognised; lead-containing jam-jars and packings, and the lead-foil used for wrapping tobacco and chocolate, have all been incriminated at various times. Though very few reports have been made of lead being carried by snuff, the structure of the upper respiratory tract is favourable to its absorption. Thus Stadler [1] has described the death of a woman through the habitual use of snuff wrapped in a metal foil containing 89 per cent. lead; the snuff was apt to be moist, and the sample examined contained 1·75 per cent. of the metal. A still more direct hazard is reported by Dr. Joseph Uttal in an account of three recent cases in New York.[2] The patients were all Jews from Eastern Europe, among whom snuff-taking is common, and were all suffering from chronic lead poisoning caused by the same brand of snuff, a cheap product which was adulterated with lead chromate and lead oxide to improve its colour. The lead content of the mixture was actually 3·4 per cent. The commodity was promptly put under embargo, but the Food and Drugs Act in the States does not include snuff in its scope, and it is said that no effort is made to prevent its adulteration.

THE CANCER CAMPAIGN IN MANCHESTER.

THE Manchester Committee on Cancer was founded in 1924 to establish a single and properly coordinated effort for cancer research and investigation. A public appeal for £20,000 was launched in 1925 and about £12,500 was received. A report of the work carried out during the last 12 months has just been published.[3] The University has afforded facility for close coöperation with its laboratory workers and research there has been directed towards the cause of mule-spinner's cancer. In addition, grants have been made to Dr. K. V. Bailey for work on cancer of the cervix, and to Dr. J. B. Duguid for investigations into the incidence of intrathoracic tumours.[4] Two special investigation officers, Dr. Gretta Wardle and Dr. John Murray, were appointed to organise regular and complete records and regular observation of cases of cancer in the city, and the

collection of histological material from hospitals, and to work on the lines of the Minister of Health's inquiry into cancer of the breast. The Committee also undertakes public education on the subject of cancer. In the winter of 1926–27 a course of 12 post-graduate lectures was arranged for medical men, and leaflets have been issued to the public. More funds are urgently needed and the Lancashire, Cheshire, and North Wales Council of the British Empire Cancer Campaign is launching an appeal this month. This Council was formed in November last by a combination of existent Cheshire, Liverpool, and Manchester Committees, and on March 6th Prince Henry, as its President, addressed meetings at Liverpool and Manchester to arouse public interest. Of the total funds subscribed, 5 per cent. will go to the national campaign, whilst the remainder will be used locally for research and treatment.

WHO'S WHO IN THE NURSING WORLD.

Mr. H. E. Smithers, late general manager of the Scientific Press, Ltd., has just brought out a useful little year-book of the nursing profession. In his preface he remarks that it was not until the exigencies of the Great War that nurses invaded the columns of well-known books of reference, and even now there is no publication supplying authoritative details of women who have made a mark or hold high rank in the nursing world. That is the occasion for the issue of the present volume, and although the personal details contained in it are unequal, that is not altogether the fault of the compiler, who expressly asks for help from outside in any later issue. Before coming to the list of names the reader will find more than a hundred pages of tabular matter relating to nursing services, institutions, societies, clubs, journals, and training schools, giving the latest information and arranged conveniently for reference. The general reader will welcome the reproduction of the various medals and badges which nurses and midwives are now entitled to wear and which should distinguish them clearly in the public eye from others masquerading as such. The year-book is published by the H. Edgar Smithers Publishing Company, 139, High Holborn, London, W.C. 1, at the price of 5*s*. It is proposed to issue it yearly in the first week of January.

A SCOTSMAN AT THE RUSSIAN COURT

A NOTE on Sir James Wylie, who gained respect for British medicine a hundred years ago in Russia, was read by Dr. Robert Hutchison, his distant relative, at the Royal Society of Medicine on March 7th. Born at Kincardine in 1758, Wylie studied at Edinburgh and Aberdeen, and went to Russia soon after graduating in 1794. At this time there was almost no organised medical profession in Russia, and for the service of the Court and the nobility, medical talent was mainly drawn from abroad, often from Scotland. Wylie remained for a time undistinguished in the country of his adoption, but eventually made his name by treating one of the Czar's favourites. This person had developed an abscess in the front of the neck, and Wylie—alone of those called in consultation—had the courage to open it. The patient was immediately relieved, and the Czar Paul was so pleased that he at once made the Scotsman a Court physician. Later, when Paul was assassinated, the physician was tactful enough to say that if he had escaped violence he would soon have died of apoplexy, and thus he became a great favourite of the successor, Czar Alexander. Wylie did much work in military surgery in the many wars of the period, at Borodino and elsewhere. He took a leading part in founding the Medico-Chirurgical Academy of St. Petersburg, and in 1818 was made Director of the Army Medical Department. It was then thought a great credit to Britain that one of her sons should have organised civil and military schools of medicine in Russia, and secured for the soldier a care and attention to which he had formerly been a stranger. Wylie was very eccentric and extremely frugal; he was unmarried, and left the whole of his wealth to the Czar, who therewith founded the large military hospital, "The Michael Clinical Hospital of Baronet Wylie" at St. Petersburg. He came to England with the Czar, and was knighted by the Prince Regent, later being made a baronet.

FEES FOR THE EXAMINATION OF CASUALS.

"VAGRANT" writes: I should be glad if any of your readers who are poor-law medical officers would inform me of the arrangements they have made with their respective guardians as to fees for the examination of casuals up to March 31st. The Minister of Health states that "a reasonable fee will be paid," but he does not state the amount. Under the Vagrancy Act these casuals are entitled to leave a workhouse at 9 A.M., and the examination of them at that hour causes considerable dislocation of a morning's programme. I understand that some men are getting 1*s*. per casual, while others are being paid 5*s*. per day. My guardians have asked that the matter be left till March 31st, and it appears to me that I also may be left.

A SPANISH REVIEW OF MEDICAL LITERATURE

As this volume [1] is apparently the first definite attemp made to enable the medical profession in Spain to ava themselves of foreign work, it certainly deserves a welcome Printed on the cover is a statement that it is intended t make its contents representative of "the whole medica efforts of the world." There are about 180 separat articles derived from some 40 publications, nearly half o which are German, and seven of these furnish over 80 items Of the rest 50 are French, a dozen English, four Swiss, an two Scandinavian. The United States, Italy, and the res of the world are not represented at all. It is clear, therefore that the editors will have to enlarge the scope of succeedin numbers considerably if their claim to represent the world medical output is to be substantiated, and no doubt thi will be done as the work expands. It will also need cor siderable modification if it is to be a convenient work o reference for the practitioner. At present there is no mean of finding a particular item without going through the who volume. There is no index and nothing to show that th subjects are grouped, as the groups are not divided or show by headings. Elaborate arrangements are made by means o a key page at the end to help the reader to index his extract when found, but nothing to help him to find them. Th method of printing on paper boards up and down the pag makes the book difficult to handle for quick referenc and but few, we fear, will be found to cut up the who and card index it which seems to be the idea in adoptin this form. The extracts given range pretty well over th whole field of medicine and seem to be adequately tran lated; it is much to be hoped that by expansion and alter tion the editors may bring this publication up to the lev which they announce on the cover.

TREATMENT OF PNEUMONIA BY GLUCOSE.

IN a recent paper [2] Dr. Ralph Lynch and Dr. Bru Webster, of Montreal General Hospital, describe some resul of treating pneumonia with intravenous glucose. It h been shown, they say, that this is the one remedy which w combat myocarditis produced experimentally in dogs b injecting increasing doses of diphtheria toxic. Taken conjunction with the fact that metabolism in pneumonia increased from 20 to 50 per cent. above normal this seem to justify trial of the treatment in human beings. As soo therefore, as the diagnosis was established the patients we given an intravenous injection of 250 c.cm. of 20 per cen glucose saline solution and administration of the sugar w continued once daily—or twice in very serious cases—un 24 hours after the crisis. At the same time glucose soluti flavoured with lime, lemon, or orange, and meat broths, wi a total caloric value of 3600 per diem, were given by t mouth. No very definite conclusions were reached for or 11 cases were treated, but it was thought that the treatme may have been instrumental in saving the life of two of t patients.

[1] Bibliographia Medica Chirurgica, No. 1, bimonthly. Directe Dr. Leon Cardenal y Pujals. Madrid. 1927. Pp. 96. 70 peset yearly. [2] Jour. Canad. Med. Assoc., 1928, xviii., 52.

ROYAL MEDICAL BENEVOLENT FUND.—At the la meeting of the Committee 61 cases were considered a £1057 voted to 51 applicants. Since the beginning the year £2203 has been made in grants to urgent cases distress. The demands for help increase and subscriptio are very urgently needed; they should be sent to he treasurer, Sir Charters Symonds, at 11, Chandos-stre Cavendish-square, W.1. The following are notes on a f of the cases relieved at the last meeting:—

Widow, aged 39, of M.B. Aberd. who died in December, 19 The husband was just getting out of financial difficulties, hav recently started a new practice, when he fell ill and died cancer after a year and a half of illness. The practice was s for £500, all of which went to pay his debts and the expenses the illness. The widow has been left with a boy, aged 14, a a capital of only £45. Voted £24 and case handed to Guild, who will try to find work for the widow.

Widow, aged 54, of M.D. Camb. The husband was annuitant of this Fund. At his death the pension from Eps and from the Freemasons ceased, and his widow has been l absolutely destitute and homeless. She has found work return for board and lodging, which will give her time to l for a salaried post. Voted £26.

Daughter, aged 58, of M.R.C.S. Eng. Has supported her and her delicate sister by literary work since the death of father. In 1926 she fell ill from overwork and her living we Gradually she has sold all she had, and now she and her sis are living in lodgings for which they pay £1 a week. T covers the rent of the room and the food for the two. I all they can afford. Voted £26.

Daughter, aged 65, of L.R.C.P. Edin. Was working a governess in Russia at the time of the Revolution; was for to leave and lost all her savings. She has returned to country at an age when it is impossible to continue her wo Her income in all is only £60 a year. Voted a further £26.

Lumleian Lectures

ON

EPILEPSY.

The Lumleian Lectures, 1928, delivered at the Royal College of Physicians of London

BY JAMES COLLIER, M.D. LOND.,

FELLOW AND COUNCILLOR OF THE COLLEGE; PHYSICIAN AND LECTURER ON MEDICINE, ST. GEORGE'S HOSPITAL.

LECTURE I.

Delivered on March 22nd, 1928.

MR. PRESIDENT AND FELLOWS OF THIS COLLEGE,—I am fully sensible of the high honour which this College has conferred on me in selecting me to give the Lumleian Lectures for this year. I wish to express to you my deep appreciation of the honour and my thanks.

I have chosen as my subject "Epilepsy" because this seems to me an opportune moment to review this symptom-complex in general, for there has been much written of late years both in this country and abroad upon epilepsy and upon closely allied conditions which has brought to light some new clinical facts and many ideas widely divergent from those conceptions as to the nature of epilepsy, which were formerly held to be orthodox. A few of these hypotheses taken at random may here be mentioned as showing that there is a necessity at the present time to make an analysis of the opinions held by authorities and to make the attempt to bring them into line, though they are sometimes widely divergent, and to produce a useful working theory.

There is Foerster's conception that the epileptic attack may have its starting-point, and therefore its locus morbi, in any part of the nervous system, both peripheral or central. There is Oppenheim's conception that epilepsy is a toxicopathic malady with cerebral manifestations. There is the book of Lows and Bond published last year describing epilepsy as "a functional mental illness amenable to psychotherapeutic measures." And while Hartenberg has made his theory widely known that the initial and essential event in every epileptic attack is a cessation and loss of function, all positive phenomena such as hallucinations and convulsions being referred to "release phenomena" occurring in lower levels of the nervous system no longer under control, Gordon Holmes holds stoutly to the cerebral cortex as the site of commencement of epileptic phenomena, to excitation as the physiological process, and to the "gunpowder and match" hypothesis of tradition.

Adie has done excellent work in helping to separate the very real syndromes of "Pyknolepsy" and of "Narcolepsy" from the idiopathic epilepsies, among which they have often remained unrecognised, and contends that the former is a disease "sui generis," and that it has no connexion with, and does not mix with, epilepsy.

Sutherland contends that the attacks which may occur in patients with heart-block and in patients with paroxysmal tachycadia, in which attacks I believe almost every phenomenon known in epilepsy has been described in one case or another, have no connexion with epilepsy whatsoever, but that they are simply the results of lowered blood pressure.

Meanwhile I have been contending for some common pathological factor which will serve to explain the identity of the train of symptoms which make up idiopathic epilepsy, with those which may occur in other disordered bodily states such as uræmia, cholæmia, hypoglycæmia, rickets, &c., and with those which sometimes occur, but with a strange inconstancy, in every kind of lesion in any position in the cerebral hemispheres, even in simple lack of development of the brain.

In all these hypotheses there is some element of truth and of value. My interest in the subject of epilepsy has always been deep, and I am fairly conversant with the clinical manifestations and treatment of this malady as met with in hospital and private practice, but I have no personal experience of the institutional treatment of epilepsy.

In these lectures, which must of necessity reflect my personal conception of epilepsy, gained from careful consideration of clinical facts which I have myself observed, I shall attempt the argument that the clinical phenomena met with in idiopathic epilepsy, in epilepsy from local lesions of the brain, and in the symptomatic epilepsy occurring in disordered metabolic states, in general diseases and intoxications, are identical and are truly indistinguishable. And that those occurring in narcolepsy, migraine, vaso-vagal attacks, idiopathic syncopal attacks, and perhaps also in tetany are phenomena of the same order and are closely allied to those of epilepsy with which they occasionally mix. And that there is one pathological factor which is common to all these conditions, and this is hypothesised as a metabolic dyscrasia, the nature of which is not always quite the same and therefore different clinical syndromes occur in which the prognosis varies.

THE NATURE OF EPILEPSY.

Epilepsy is common in birds and it affects all mammals; the horned cattle rarely, the carnivora and the primates more commonly. In all these epilepsy occurs just as it is met with in man, as an idiopathic disease; or resulting from local lesions of the brain; or symptomatic of general diseases and intoxications. The ætiological factors seem to be the same as in man. Hereditary transmission was well shown in the case of the prize bull recorded by Le Notte, who was an epileptic, for the best specimens of his progeny were invariably epileptics. Cruzel's cow was an epileptic who gave birth to three epileptic calves consecutively, and Otto's epileptic bitch was wont to produce epileptic puppies. Hutyri and Marck lay stress on the teething convulsions of young dogs and young pigs and the development therefrom of established epilepsy, and they point out the major incidence upon rickety animals, and they record puerperal convulsions in horses and cows, in dogs and in pigs. The clinical manifestations are the same with major and minor attacks, local and general attacks; epilepsy occurring exclusively in sleep, as in Haltenbach's cat; presumable auræ from the evidence of terror and cries of distress from the animal immediately prior to the fit, or perhaps he takes to his heels and bolts to fall in a fit after the manner of the classic "cursive" epilepsy in man. There is also "reflex" epilepsy, well known when wounds, especially of the withers, horns and hoofs, have cicatrised; post-epileptic paralysis and the usual train of post-epileptic phenomena; and also status epilepticus. Further, the epilepsy so occurring in animals is ameliorated by the administration of the bromides.

So far as the so-called "idiopathic" epilepsy which thus affects man and the animals is concerned no pathological changes have been found upon which any hypothesis as to the nature of epilepsy can be built up. The findings have been for the most frankly negative, or such changes as have been found in severe and long-standing cases as may be reasonably attributed to long-lasting disorder of function. Attention has therefore turned to the possibility of finding an explanation of epilepsy in some perversion of the chemistry of life—some metabolic dyscrasia which may lead to the presence of substances within the system which act upon the nervous system as do the convulsant poisons and which may further, by depriving the nervous system of its customary activators, cause in some cases a progressive impairment of the higher functions of the nervous system. Experimental investigations upon these lines have been at times suggestive but not very fruitful. Donath thought that he had found the essential convulsant poison in choline, and Mott showed that a watery solution of choline applied to the surface of the brain would produce convulsion and also post-convulsive transient paralysis. Choline, however,

seems to be a product of degeneration within the nervous system and cannot, I think, be found within the body in idiopathic epileptic states. Krainski, doubtless arguing from the occurrence of epileptic phenomena in uræmia, suggested that ammonium carbamate, produced within the system from disorder of metabolism, was the epileptogenous agent, and this is present in the blood of uræmic persons and to a small extent in some epileptics. Hahn, Masser, Nercki, and Pawlow have shown how readily fits may be produced in dogs by the injection of calcium and sodium carbamate and, more recently, Bisgood and his co-workers have put forward the hypothesis that the disturbance of metabolism in epilepsy is a "dis-regulatio ammoniaci" depending upon the disturbance of the function of the parathyroid glands, and J. Madsen following them, claims benefit from a calcium-parathyroid treatment in epilepsy, though he does not consider that epilepsy is a disease of parathyroid origin. He thinks that the parathyroid gland acts as an ortho-regulator as opposed to a dys-regulator of ammonia metabolism, and that a disturbance of ammonia metabolism is a factor in the production of epilepsy.

Some highly interesting and suggestive experiments have been made by Pagniez, Mouzon, and Turpin upon the toxicity of the serum of epileptic patients at the time of the attack. They found that when such serum was injected into the heart or into the carotid artery of animals, a series of convulsions occurred which lasted some half an hour and often ended fatally. No such convulsions occurred in any of the control animals into which healthy serum or the serum from uræmic patients or patients afflicted with general paralysis was injected. These experiments suggest very strongly that the determining agent for the epileptic attack is present in the blood, but only when the attack is about to occur and not at other times.

Bossard has put forward the theory that the immediate cause of the epileptic attack is "anaphylactic shock" from some product of disordered metabolism, and that the local effect thereof is upon part of the cerebrum, while the general effect is shown by the fall in the blood pressure and the leucopenia which he claims invariably and immediately to precede every epileptic attack of any magnitude. This theory is enticing, for it compares the rapidity of onset of the epileptic attack with the well-known dramatic suddenness with which anaphylactic phenomena may occur. It is in line with the well-established hypothesis that puerperal convulsions—which I prefer to call puerperal epilepsy—are caused by anaphylactic occurrences within the brain. It corresponds with the explanation of migraine—a malady very like epilepsy, often associated with epilepsy and sometimes hardly distinguishable from epilepsy, which is current at the present time, that this malady is due to local anaphylaxis in the brain with swelling of the brain and at times local disturbance of function. A similar swelling of the brain at the time of the epileptic attack may well account for the headache and mental dullness which often follows.

Bossard's hypothesis is a suggestion as to how a metabolic dyscrasia or toxic condition of the blood might reasonably act upon the nervous system, if indeed such dyscrasia or toxæmia exist. It is not contradicted by any experimental evidence, and upon it all the clinical manifestations of epilepsy can be intelligibly explained. It is a useful working hypothesis for the present. But by far the most important statement he makes is that the blood pressure falls with the onset of the attack, or rather that one of the essential features of the epileptic attack is a fall of blood pressure. If this is true it is of far-reaching importance, for it does away with the hard-and-fast line of separation between epileptic manifestations and syncopal attacks which has been laid down by many authorities, including Gowers, who argued that there was no conspicuous fall of blood pressure in an attack of epilepsy, and who stated that he had had his fingers upon the pulse many times at the moment of attack and had observed neither alteration of rate or tension. I shall have occasion to remark later on that such a strict separation between syncopal attacks and epileptic attacks is clinically difficult from several points of view and that in my opinion it is rather artificial than real.

Such an initial fall of blood pressure, if proved to be constant in the epileptic attack, would, I hope, serve to further rid our minds of that explanation in pathology for so many ill-understood diseases—arterial spasm. There is certainly pallor of the face with the onset of many epileptic attacks, and pallor of the brain has been noted by several observers. Indeed, Foerster makes the wonderful statement that he has on one hundred occasions witnessed an epileptic fit upon the operating table when he has had the brain exposed, and that he had noticed the sudden pallor of the brain with the onset on every occasion. He was, of course, arguing for arterial spasm.

Following upon this work, attempts have been made to desensitise the epileptic patient between his attacks by the injections of his own blood taken at the time of the attack, and though good results have been claimed, we have not been able to confirm them at Queen-square. The well-known tendency for epileptic fits to disappear for the time being during acute infections and after the injection of foreign serums and proteins, led to the researches of Tine and Santanoise, who have shown the existence in their epileptic patients of alternating periods of sensitivity and immunity. Protein therapy has consequently been used for the treatment of epilepsy by many hands without any convincing result.

The endocrine organs have been searched histologically with great care in epileptics by Schou and Susman with negative results. On the clinical side one finds the occurrence of epilepsy in some of the cases of pituitary disease, both in the acromegalic type and in the Fröhlich type, but especially, I think, in those presenting arrest of bodily growth in childhood which correspond with Lorrain's type of infantilism.

In some cases in which thyroidectomy has been performed epilepsy has been observed usually associated with tetany. In others there have been severe attacks of tetany with loss of consciousness and incontinence of sphincters, suggesting a blend of epilepsy and tetany. In the case of a middle-aged woman admitted under my care at the National Hospital as a case of epilepsy, a very extensive thyroidectomy had been performed; there were no signs of myxœdema. There were very typical attacks of tetany, but there were also attacks in which loss of consciousness and incontinence occurred which were very like attacks of "tonic" epilepsy. A calcium and parathyroid treatment brought about the disappearance of the symptoms in this patient. These events are in line with the experiments of Horsley with panthyroid extirpation in monkeys and with the parathyroid removals of Biedl, in which both tetany and epileptic manifestations resulted. The absence of the parathyroid element is now held to be responsible for these symptoms, which, so far as I am aware, have never been observed in any case of myxœdema.

Metabolic Disturbance as a Cause of Epilepsy.

I submit that there are many clinical features of epilepsy which argue strongly in favour of a metabolic disturbance as the essential cause for epilepsy.

1. In the first place there is the very common incidence in early infancy when the personal metabolism may not as yet be strongly organised, nor the developing brain highly stable, and the very important influence which so definite a metabolic disorder as rickets has, in determining the incidence of epilepsy. All great authorities are agreed that infantile convulsions often associated with rickets are the most important of all the known antecedents in idiopathic epilepsy which is personal and not inherited. There is, again, the incidence at the time of puberty when important metabolic changes may be presumed to

occur, and again, a small incidence in the degenerative period of life when metabolic regulation may be failing. Then there is the periodicity of epilepsy with its often amazing regularity, the attacks occurring always at night or at regular intervals, or only at the menstrual epochs. And, more strikingly, those cases in which batches of fits at long intervals occur—sometimes many in a day—and during the long intervals nothing will induce the patient to have a fit. Surely such periodicity is more reasonably explained on the grounds of a metabolic dyscrasia—now present, now absent, than upon any other hypothesis which has been advanced.

2. It is usual for the epileptic woman to have complete immunity from the attacks during pregnancy, and I submit that this fact can only be explained on the basis of the correction of a faulty metabolism in the mother by that of her fœtus. The cessation of epileptic attacks during pregnancy is not confined to idiopathic epilepsy, but it has occurred under my observation in many cases of epilepsy from local organic disease of the brain, and I have also seen several cases in which the epileptic manifestations of local lesions of the brain have appeared directly after the termination of pregnancy, as if the pregnancy had held these symptoms back. I wish particularly to emphasise this point, for I shall attempt to argue later on that there is metabolic dyscrasia present as a second factor in every case of organic lesion of the brain which presents epileptic manifestations. On the other hand, it is common knowledge that epilepsy may occur only during pregnancy and with repeated pregnancies, and this form, I think, surely belongs to the class of eclampsias due to anaphylaxis from fœtal products.

3. Status epilepticus is, in my opinion, only explicable on the grounds of an acute autotoxic process. It closely resembles experimental convulsions from the exhibition of convulsant poisons, and it is very closely akin to the convulsions of uræmia and of eclampsia. It is the commonest event by which epilepsy in itself causes death. It arises sometimes in an epileptic subject who has had no fits for a very long time, and whose cerebral condition might therefore be deemed to be more stable than in the epileptic who has frequent fits. Sometimes over-exertion is the immediate exciting cause, sometimes the discontinuance of medicinal treatment by the bromides or other remedies. Sometimes no exciting cause can be attributed. The attacks begin and recur with increasing frequency and severity in spite of the apparent complete abrogation of cerebral function, and death is a common result, notwithstanding any treatment that may be adopted. Now I have in several cases of status epilepticus arrested the convulsions, restored the patient to consciousness and secured adequate nutrition, and yet death has occurred in a few days from exhaustion with a rising temperature and pulse-rate. It is most important to bear in mind that in these cases the autopsy showed the most acute and intense fatty degeneration in the cardiac muscle. So far as I am aware this change in the heart muscle is the invariable finding in status epilepticus, and this was emphasised by the late Sir Frederick Mott, who told me that in his rich experience he had never seen an autopsy upon any case of status epilepticus in which this condition of the heart muscle was not conspicuous. Such fatty degeneration must surely be the result of an acute toxæmia, which is at the same time the cause of the external manifestations of status epilepticus. It cannot be ascribed to an effect of continued convulsion and lack of nourishment, for the amount of energy expended from convulsion in status epilepticus in no way exceeds that put out by a labourer in a day's work, and is incomparably less than that which may be exhibited by an acute maniac, without sleep and without food, and without signs of myocardial disturbance even after many days.

It seems to me that there is another condition occurring in epilepsy to which the term "status epilepticus" should justly be applied. I have met with it only in epileptics who show mental deterioration. The patient, without cause, and perhaps after signs of increased mental aberration, becomes dull, ceases to take food, and lapses into coma with terminal pyrexia which ends fatally. This in reality is status epilepticus without the convulsions, and if the convulsive form be comparable with uræmic convulsions, then this second variety may be reasonably compared with uræmic coma.

4. It is a remarkable fact that the habitual epileptic person shows immunity from so many of the common diseases which are the plagues of the world—such as the specific fevers of childhood, tuberculosis, pneumonia, and carcinoma. And the epileptic shows this immunity in common with the subjects of infantilism, or of idiocy or of cerebral diplegia, in all of which diseases we have grounds for believing that a perversion of bodily metabolism is the essential cause. And this fact favours the argument that in the epileptic subject metabolic perversion is a fundamentally important factor. I suggest that the bodily peculiarities and the somewhat aberrant mental make-up which is seen in some habitual epileptic persons is the expression of this same metabolic error, and that the mental aberration, mental deterioration, and terminal dementia are results of the same process, either by way of deprivation of activators necessary for the maintenance of cerebral function or long-continued poisoning. The prodromal symptoms of the epileptic seizure—sometimes in the way of exaltation, excitement, and restlessness, sometimes expressed in headache, lethargy, and feelings of bodily illness—are surely the indications of some general bodily change which culminates in the paroxysm.

Mental deterioration, mental aberration, and terminal dementia occur only in some of the cases of epilepsy. In others the highest degree of mental attainments may be acquired and preserved throughout a long life. Nor does the condition of mentality bear any constant relation to the frequency or the severity of the epileptic manifestations. There is one clinical variety of epilepsy, for example, pyknolepsy, in which, though the attacks are of very frequent occurrence for years together, yet mental deterioration is said never to occur. I have seen many examples of this condition. On the other hand, there are many cases in which epileptic attacks, though mild and not very frequent, are followed by progressive and irrecoverable mental deterioration. Clearly, then, the epileptic occurrences are not responsible for the mental deterioration, but they must be the result of some concomitant metabolic fault akin to that which is supposed to give rise to the progressive mental deterioration in dementia præcox. It is an important fact that epilepsy is of common occurrence in dementia præcox.

Organic Epilepsy.

The occurrence of epilepsy in connexion with every conceivable variety of local disease of the cerebral hemispheres is a difficulty in the conception of a fundamental factor for epilepsy in a disordered metabolic state. This organic epilepsy has for the most been considered as something quite separate and apart from idiopathic epilepsy, and as having a different clinical aspect and ætiology, and requiring a separate description, and as amenable to surgical methods of treatment. This opinion, which is still widely held, has, I am sure, impeded the progress of our knowledge of epilepsy, for there is in reality no difference whatsoever between the clinical manifestations of epilepsy resulting from organic disease of the nervous system and those of idiopathic epilepsy. It is traditional at the National Hospital that when you, Mr. President, first took charge of the out-patient department there you discovered in a very short space of time a considerable number of cases of organic disease of the brain among the patients who had been passed by your predecessors as cases of idiopathic epilepsy. I suggest that you did not do this from any peculiar nature in the attacks which these patients had, but from your skill

in the use of the ophthalmoscope. I have myself personally observed every known feature characteristic of idiopathic epilepsy in cases of organic disease of the brain. I may here mention three examples of the more rare events. First, minor attacks. I have seen the most characteristic attacks of "petit mal" with momentary pallor and loss of consciousness instantly regained commence for the first time and recur frequently in the course of cerebral tumour, and in one case where the tumour was successfully removed from the right temporal region the attacks permanently ceased. Secondly, "myoclonus epilepsy" or "epilepsia continuans." This somewhat rare condition has been described as an idiopathic epilepsy with myoclonus superadded, and it has been called a disease "sui generis." Muskens has quite recently claimed that the myoclonus is not a very uncommon manifestation of idiopathic epilepsy, and with this opinion I entirely agree. The following case emphasises the occurrence of myoclonus epilepsy as symptomatic of a local lesion of the brain. There is at the moment of writing a young woman under my care at the National Hospital, who several months ago commenced to have local epileptic attacks, without impairment of consciousness, in the right foot and leg. Thereafter the right leg has developed a spastic paralysis which has increased to the extent that she can hardly walk. The usual signs of pyramidal tract involvement are present. The attacks occur only in the night. But all day long the muscles of the right leg are twitching just as one may see the muscles of a patient with uræmia twitch. The twitching does not extend above the iliac crest. Now and again the muscular contractions become more massive and the limb moves with the short shock-like movements which characterise myoclonus. The presence of an organic lesion of the brain, probably a neoplasm, is incontrovertible in this case, and that this lesion is responsible for the local myoclonus-epilepsy is also incontrovertible. So far as I am aware no case of this nature has hitherto been recorded.

Status epilepticus has not usually been included in the descriptions of the manifestations of organic epilepsy, if I may exclude the repeated convulsions which may occur in acute encephalitis and in general paralysis. But it may certainly result from local lesion of the brain. Quite recently a patient was admitted to the National Hospital as a case of severe idiopathic epilepsy of two years' duration. Meticulous and repeated examination did not reveal any sign suggesting that an organic lesion was present. The fits increased in frequency, and during the last 12 hours he had 60 fits, and there was no return of consciousness between the attacks, so that he was indeed in a condition of status epilepticus. At the autopsy a frontal tumour was found.

On the other hand, the peculiarity in the epileptic attacks which have been hitherto claimed as characteristic of organic disease of the brain, such as local commencement of hallucination or convulsion, slow spread or restriction of the disturbance to one region, with retention of consciousness are all common features of idiopathic epilepsy, notwithstanding the confident statements to the contrary which have recently been made by J. P. Martin and others. A majority of idiopathic epileptics have local fits at some other time or other. Some have occasionally the local aura which is not followed by the usual attack, others have occasional local convulsion, while in a few local attacks predominate.

As an example of the last condition, a child who was under my observation in the out-patient room at Queen-square for many years, showed us, on one occasion or another, during the few moments of her presence for examination, beautiful restricted attacks of Jacksonian convulsion, in one or the other side of the tongue, in either side of the face, in either shoulder or in either hand, in either side of the abdomen, and in either leg, both upper and lower. There was never any impairment of consciousness, and only on rare occasions had the convulsion become general. One gained a greater experience of local epilepsy from this one case that one would do from an averag 200 cases of cerebral tumour. This patient recovere and is now the mother of a growing-up family.

I have seen every conceivable variety of loc attack, both sensory and motor, to occur in idiopath epilepsy, and I am in the habit of teaching, perha too dogmatically, that the commonest cause Jacksonian epilepsy is idiopathic epilepsy, but th actually is my individual experience. I have former years assisted at operations for craniectom in cases of Jacksonian epilepsy where nothing wha ever abnormal has been found, and when subsequent the attacks ceased for ever, as often happens in loc idiopathic epilepsy, either spontaneously or durin the administration of the usual remedies, the case w claimed as a cure by surgical measures, though wh the surgeon did besides introducing a few adhesio and a little scar tissue escaped me.

Epilepsy results only in a small minority of organ lesions of the cerebrum, whatever may be the natu of the lesion and whatever may be the situation that lesion in the brain. With some lesions it very rare indeed. In disseminate sclerosis, f example, though lesions of the brain, and very oft of the cortex, are common, epilepsy does n occur in more than 1 in 500 of the cases. Wi wounds of the brain the subsequent inciden of epilepsy is in about 4 per cent. of the case according to the statistics of the Great War. cases of cerebral tumour the incidence is less tha 10 per cent., even with the rapidly growing end theliomata that press into the surface and whi seem to be the most epileptogenous of the lesions with a localisation in the uncinate lobe, which seen to be the most susceptible region.

There is no lesion of the brain that will certain produce epilepsy, whatever be its nature or positio There is hardly a lesion of the brain of any natu which has not produced epilepsy. Of ten tumou of the brain identical in nature, size, rate of growt and position, one produces epilepsy early and co tinuously, while the other nine do not. Of 20 simil wounds of the brain one is followed by epilepsy ar the others are not so followed.

Obviously, therefore, it is not the lesion of t brain alone which is responsible for the epileps There must be some other factor which, together wi the brain lesion, can produce epilepsy. This seco factor has been sought for in some peculiar irritati quality of the lesion, some weird potentiality f setting a train of gunpowder on fire, which, I submi is picturesque enough, but too much derived from t effect of a pair of faradic electrodes upon the cerebr cortex. It has been sought in adhesions and tiss tractions and dislocations which might be remedi by surgical measures. But we have such goo knowledge of the extraordinary degrees of tiss dislocation, traction and adhesion, which the brain w put up with without any epilepsy or, indeed, witho any disturbance of its function at all, as in hydr cephalus, injuries to the brain, and adhesive meni gitis. It has also been sought in the local liberati of poisons of a convulsant nature—choline, f example—from the decaying nerve elements in t region of the lesion. But epilepsy is no more consta in cases where we may presume such decay to occurring as with others in which the likelihood decay is remote—cerebral agenesia, for examp and in such diseases as progressive muscular atroph in which we know well that progressive decay the elements of the ascending frontal convoluti is proceeding rapidly, epilepsy is unknown. Wh listening to Sir Percy Sargent's presidential addre upon the causation of epilepsy from local lesions the brain a few years ago, I could not help feeli that he was very ably saying the very last word support of an utterly lost cause.

I submit for your consideration that the seco factor which we are seeking for as the cause of epilep from local lesion, since the local lesion of itself seer impotent to produce epilepsy, is in reality the sam disorder of metabolism which I have theorised as t

fundamental cause of idiopathic epilepsy, but existing in minor degree, so that there are no spontaneous outbursts until the local lesion of the brain is added—a sort of potentiality of chemical make-up which favours the occurrence of epilepsy, great in those who are frank epileptics, less but present in varying degrees in those who develop epilepsy from local lesions of the brain, or in connexion with general diseases and intoxications, or in connexion with such cardiac derangements as heart-block and paroxysmal tachycardia, and absent in a great many who will not, however provoked, show epileptic manifestations.

This idea of the unity in cause of idiopathic epilepsy, organic epilepsy, and symptomatic epilepsy which I have thought about for some years has recently received some support in the experimental work of Dandy and Elman at the Johns Hopkins Institute at Baltimore, who set out to determine whether localised injury of the brain rendered cats more susceptible to toxic convulsions and whether the site of injury had any important bearing upon the nature of the convulsion so produced. The injuries employed were local cortical and subcortical extirpations, simple incisions into the convolutions, and the embedding of small foreign bodies locally beneath the cortex. Several weeks later, when the wounds had healed and the animals were in perfect health, a 10 per cent. solution of wormwood oil was introduced into the stomach by tube in exact doses. These authors found that one-third to one-seventh of the dose of the wormwood required to produce convulsion in normal cats would excite attacks in the animals which had a lesion of the brain. Injuries to the central convolutions were found to be much more potent in rendering the cats susceptible to the absinthe convulsions than were lesions of the occipital lobes, yet lesions in any part of the cortex were in some degree effective. A minimal convulsive dose produced unilateral convulsion corresponding with the side of the brain injured and without loss of consciousness, and when they had the luck to hit on exactly the right minimal dose the convulsion remained strictly local. With the small doses necessary to produce convulsions in the animals with cerebral lesions, the general absinthe effect of restlessness and irritability working up to the convulsions and which was always present in the normal cats, was never observed. These experiments show that a local lesion of the brain not in itself epileptogenous, can in conjunction with a disturbing agent in the general bodily circulation, again not in sufficient dose to be epileptogenous, produce both local and general epilepsy. And that is the proposition which I have placed before you as a possible explanation of epilepsy as occurring from local disease of the brain.

Symptomatic Epilepsy.

May I now draw attention to those happenings, usually called convulsions, which occur in so many conditions of bodily disease, from the convulsions of infancy and those which may usher in acute infections and which seem interchangeable with the condition of "rigor," to the nervous manifestations of uræmia, eclampsia, and tetany, premising on high authority that there is not one example of such convulsion which has not continued in some recorded case into an established epilepsy. With these convulsions you will find, on occasion—I will not say commonly—most, if not all, of the clinical phenomena which characterise epilepsy; major attacks and minor attacks, local attacks and general attacks, auræ, sensory and motor fits, and post-convulsive paralysis. Sometimes the clinical picture *qua* epileptic manifestations is indistinguishable from epilepsy proper. How many times has a patient been treated for years, and with success, as an occasional epileptic, when the first appearance of hæmaturia has led to a correct diagnosis of cystic disease of the kidneys. At least ten times in the O.P. room at Queen-square has a child been brought to me with a story that would have passed as characteristic of idiopathic epilepsy, when either the anæmic appearance of the patient or a finger placed upon the pulse or a look at the fundus oculi has changed the diagnosis to one of Bradford's kidney.

There is at the present time in one of my beds at Queen-square a man who has had epilepsy for many years with much mental deterioration. His fits are general and occur but rarely—they never have been frequent. His muscles twitch continuously night and day in a manner characteristic of the uræmic state. There is no uræmia, but the phenomenon is identical and the cause must be nearly allied. It is called "epilepsia continuans." Similar twitching of muscles as an occasional phenomenon is, however, very common in epileptics. It may herald an oncoming attack or may occur without reference to the other epileptic symptoms.

I submit that since a train of phenomena sometimes precisely, and at other times closely resembling those of epilepsy, is well known to occur from disordered nutritional states, interference with important organs of metabolism and from infections and intoxications, all of which are productive of metabolic dyscrasia, it is a fair argument that all epilepsy may be similarly caused and that symptomatic convulsions and other epilepsy-like manifestations should be included in descriptions of epilepsy, the more so because any of the latter may persist after its apparent cause has disappeared as an established epilepsy.

THE RATIONAL USE OF DIGITALIS.

By BRUCE WILLIAMSON, M.D. Edin., M.R.C.P. Lond.,
PHYSICIAN TO THE ROYAL NORTHERN HOSPITAL, LONDON.

Authorities agree that digitalis is a valuable drug in the treatment of disorders of the heart, but much confusion and contradiction exist as to its actions and the type of case in which it should be employed. Yet in all cases there is one constant factor, and that is the action of the drug; this does not change. The varying results obtained from its use are mere expressions of the fact that different conditions obtain in the various cases, the drug-action being a constant. A study of these varying results illuminates the subject and clearly indicates the rational use of the drug.

Without some conception of the laws governing the living cell all therapeutic measures are empirical. It was to this problem of the living cell that Sir James Mackenzie gave the last few years of his life. He evolved the following simple conception[1] of cell activity, based upon a study of the less complex biological forms. He considered that the vital process in a living cell is that of the alternate discharge and renewal of its energy. This principle applies to all cells, whether they be highly specialised such as the polygonal cells of the liver, or humble supporters in connective tissue. The characteristics of the cell are fixed, and no agent can effect a change in them. On the other hand, the rate of activity of a cell, or the process of discharging and renewing its energy, is variable and liable to influence from without. The activity of a cell is coördinated with somatic requirements through specialised paths known to us as nerves, and the stimuli transmitted by nerves act by either delaying or quickening the process of recovery in the cell. Stimuli are identical and in no way specific, nor can they interfere with the characteristics of the cell they control. Drugs, in a like manner, act only by delaying or quickening the process of recovery in the cell.

The Heart.

In the heart there are three elements concerned in the rhythmic cycle—the nerves, the genetic system, and the myocardium. The genetic system is a term applied by Mackenzie to the conducting

[1] Sir James Mackenzie: Diseases of the Heart, fourth edition.

system, to stress the fact that this system does not only conduct, but also originates stimuli (see figure). Rhythm is an inherent property of this tissue, even when excised. The genetic system begins near the great veins at a node known as the sino-auricular node. This is connected with a similar node in the junctional tissue known as the auriculo-ventricular node. Thence the system is continued as the bundle of His, which runs in the septum of the ventricles, eventually losing itself in the cardiac muscle-fibres. The sino-auricular node is the most sensitive part of the genetic system and sets the pace in the normal heart. To a lesser degree the auriculo-ventricular node possesses the same faculty, and when the continuity of the system is interrupted between these two nodes the auriculo-ventricular node originates the stimuli. When a lesion lies distal to the auriculo-ventricular node the bundle of His originates the contraction. Such a condition is known clinically as complete heart-block. The genetic system may be termed automatic, but there are two controls which coördinate the work of the heart with the requirements of the body. These controls—the sympathetic and the vagus nerves—have an opposite action; the sympathetic is an accelerator and the vagus a depressor. They are connected to both the nodes, but the more highly specialised sino-auricular node is the main channel through which the stimuli pass. When the body is in exercise, the heart quickens in response to the stimuli through the sympathetic affecting this node. In sleep the heart is slowed by a similar action operating through the vagus. The third element concerned in maintenance of the rhythmic cycle of the heart—the myocardium—is the most important. The myocardium differs from the other muscle structures in that there is a continuity between its fibres, making it thereby more or less one unit. The association of the terminals of the genetic system with the myocardium is much more intimate than that found in any nerve-muscle system elsewhere in the body.

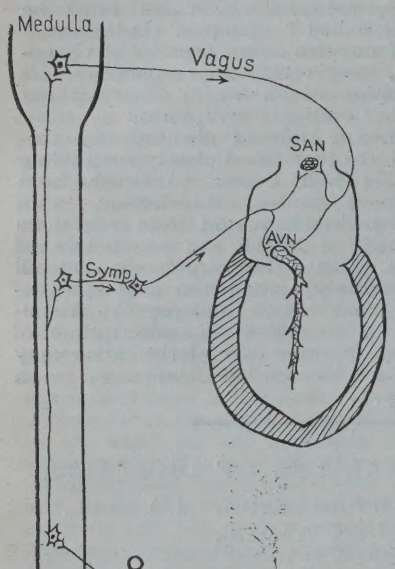

Diagram showing innervation of heart (modified from Sir James Mackenzie). Symp. = sympathetic fibres. SAN = sino-auricular node. AVN = auriculo-ventricular node.

Such are the elements concerned in the cardiac cycle. The rational use of any drug can only follow from a study of these elements in their interdependence in producing a flawless organ.

Digitalis.

The action of this drug has been described as multiple. Some text-books state that: (1) it slows the heart; (2) lengthens diastole; (3) acts directly on muscle-fibres and strengthens their contractions; and (4) increases peripheral resistance and thereby raises the blood pressure. Even a diuretic action has been attributed to the drug.

A second school of thought considers that the action is singular and that the drug acts by virtue of its property of stimulating the vagus. This, I think, is correct, since all the effects of the drug can be traced to this simple action. Stimulation of the vagus slows the heart and this increases the force of the next beat, the circulation moves more forcibly, and the blood pressure rises. The results of this increased efficiency are felt in all organs, and direct evidence is seen in the increased secretion of urine and the diminution of œdema. It is significant that clinically the presence of œdema is essential to the diuretic action. Strong support is obtained experimentally for this hypothesis. When the vagi are divided, no action of digitalis is obtained. The site of action is presumably the central termination of the nerve, for atropine, which paralyses the vagus, does not prevent the slowing effect of digitalis. It is interesting to note that division of both nerves does not affect the atropine action, and it follows that the site of action of the latter drug differs from that of digitalis in that it lies at the peripheral end of the nerve.

If the sole action of digitalis is to slow the heart, it follows that there is one indication only for the use of digitalis and that is in rapid hearts. I use the words rapid hearts in preference to tachycardia, for that suggests to many a standard of rapidity in the vicinity of 150 or more beats to the minute. At first sight this statement may appear to restrict unduly the field of therapeutics for digitalis, but a second's thought will make it apparent that the field is extremely wide. Heart failure with a slow heart is not an uncommon occurrence, but is usually beyond the reach of any drug. To administer digitalis in such a case is to invite a further degree of heart-block. Bradycardia is generally recognised as a strong contra-indication to the use of digitalis. In confining the use of digitalis to an action on the heart-rate no restriction is implied on hearts showing arrhythmia, but no direct action on the irregularity is likely to occur except where this is due to vagal influence. Where the disappearance of an irregularity which has its origin distal to the vagus-ending follows the use of digitalis the result is probably due to the improved cardiac circulation in the heart itself.

Rapid Hearts.

Rapid hearts can be considered in two groups—where the origin of the rapidity is outside the heart and where it arises within the heart. Extracardial rapidity usually arises from stimuli conveyed by the sympathetic. Examples of this group are to be found in febrile conditions and constitutional disorders. Heat itself, when applied to any part of the genetic system, even when the latter is excised, promptly increases the rate of contraction. The rapid heart in a fever may be due to this, but more probably it is due to central stimulation of the sympathetic. Fever means increased metabolism, which demands a more rapid flow of blood through all organs. In such cases the slowing action of digitalis is not obtainable. It would require an extremely potent drug-action to negative such a persistent stimulation of the sympathetic as that which occurs in a fever. It is common to give digitalis in pneumonia, but the typical digitalis effect is rarely if ever obtained. Certain authorities declare that it does not act at all, and it is certainly difficult to find any concrete evidence in support of so widespread a practice. Graves's disease provides another example of extracardial rapidity. Practically the whole of the signs in this condition indicate stimulation of the sympathetic. Again the failure of digitalis to effect any definite change in the heart condition is noteworthy, and is generally recognised. Further observations on this extracardial group of "rapid hearts" requires to be made before the value of digitalis can be rightly assessed. In the light of our present knowledge it would appear that the extra stimulation of the sympathetic in response to abnormal demands of the body—i.e., increased metabolism—is more powerful than the counteraction of any drug we possess.

The essential feature in the other group is the excessive vital activity in the cells of the genetic

system, especially in the nodes which originate the stimuli. On theoretical grounds a rapidity due to increased vital activity in the genetic system should respond well to any drug which can produce a decrease in this vital activity. This may be accomplished by action directly on the cells in situ or by stimulation of the vagus, the physiological function of which is to delay the process of recovery in the cells of the nodes. In digitalis we possess such a drug, and its rational use depends upon the recognition of these two groups of rapid hearts. In the extracardial type digitalis is of little use, probably because the rapidity results from a strong physiological stimulus of an essential nature. In the intracardial type the rapidity arises from a local cause. In this group neither the vagus nor the sympathetic is involved directly, and both may be said to be open to occupation by any drug possessing a specific action.

During an afebrile period the toxic hearts of rheumatic infection frequently exhibit a pulse-rate of 110–120 and a regular action. The cause of the rapidity lies within the heart. Dr. G. A. Sutherland [2] was the first to direct attention to the excellent results obtained from digitalis in these cases. In six cases the pulse-rate fell from 125 to 85 in three days. The benefit which arises from saving 40 beats a minute over a few weeks in a toxic heart can hardly be over-estimated. The action of the drug appears to be a simple depression of the sino-auricular node, and to a lesser extent probably the auriculo-ventricular node.

Auricular fibrillation can be divided into two groups—the slow and the rapid forms. In the slow form there is no indication for interference with digitalis. When the irregularity has been established for some time and the pulse-rate remains in the vicinity of 80, signs of circulatory deficiency may be entirely absent, and the patient may lead a useful life for years. On the other hand, a deficient circulation accompanying a slow pulse indicates a marked degree of myocardial degeneration, and the prognosis is usually extremely grave. Digitalis can bring no relief. The essential feature of auricular fibrillation is the absence of the normal sinus rhythm. This is replaced by multiple stimuli which are conducted by abnormal paths. The result is that the auriculo-ventricular node becomes subject to a bombardment of stimuli in such rapid succession that only a few stimuli are effective and the ventricles contract in response to these. Where the node is very sensitive the pulse-rate will be very rapid, and the recovery period in the cycle of ventricular contraction will be greatly reduced. Under such conditions myocardial exhaustion is only a question of time, and digitalis is of extreme value; the sensitivity of the node is greatly reduced and more stimuli are blocked. The effect resembles the conversion of a stopping train, which permits entry at every station, into a long-distance train which permits entry only at long intervals. The rate of the ventricles is reduced, but the auricles continue to fibrillate. Occasionally the fibrillation ceases; this is not due to any direct action of the drug, but is probably attributable to the better circulation in the myocardium. In this respect it is well to recall the fact that the myocardial circulation is at a maximum during diastole.[3]

Digitalisation of the Heart.

This term is employed to express the condition present in the heart when the full effect of the drug is produced. The amount of drug required to effect this is known, with variations in individual cases. Until digitalisation is established benefit is not obtained. Unfortunately the margin between toxicity and therapeutic action is small, and herein lies one of the chief difficulties of the effective use of the drug in general practice. The difficulty is real but, with regular supervision, it is not insurmountable. American writers have asserted that 15 c.cm. (3 drachms) of the tincture per 100 lb. of body-weight is sufficient to effect digitalisation. To maintain this about 20 minims a day is required, for this figure represents the daily destruction and excretion of the drug by the tissues of the body. Thus it is possible to employ relatively large doses of the drug, based on body-weight, until the required concentration is reached. Digitalis is completely absorbed by the stomach in six hours, and it is rational to give the drug four times a day until the therapeutic action is reached. Massive dosage is seldom required, nor is the intravenous route, as with strophanthin. Intravenous administration should be reserved for cases of great emergency, for the early symptoms of toxicity—i.e., headache and vomiting—which accompany oral administration are lacking. The procedure of digitalising the heart is as follows. A fresh tincture should be employed or, better still, the pure active principle such as digitalin (that made by Nativelle is very reliable). In adults it is quite safe to give a drachm of the tincture daily for two days, then 45 minims a day for the next two days, by which time the required concentration of the drug is not far distant. At this stage great care must be taken and constant inquiry into the patient's well-being should be made. The drug should be continued in doses of ℿx thrice daily till the pulse-rate falls to about 70 or 80 beats per minute, and before each administration inquiry should be made for toxic symptoms. Not infrequently the pulse will be found to assume a peculiar rhythm, which at first may cause alarm. This is due to the introduction of extrasystoles which may occur every third beat or oftener. The effect is coupling or tripling of the beats. Such a phenomenon indicates that the drug should be discontinued for the time being. As a rule the pulse becomes quite regular in a day or two.

Failure to effect digitalisation arises in many cases from a lack of appreciation of the fundamental action of the drug. An essential preliminary is the absence of undue stimulation of the sympathetic. Many subjects react with extreme facility to slight excitement, and the heart-rate increases through sympathetic stimulation. Simple isolation in a quiet room is usually effective. If the pulse-rate remains rapid despite this precaution, a thorough examination of the patient may lead to the discovery of some metabolic cause for the rapid heart. The case then falls into the group of extracardial rapid hearts, in which digitalis is of little avail.

When the heart is digitalised the precise dose required to maintain the control must be found. In the adult 20 minims of the tincture a day is usually sufficient and, with this amount, the slowing effect can be maintained indefinitely. In the typical case of failure of the circulation in the absence of fever the benefits quickly become apparent. The distressed breathing disappears, œdema subsides, and the urine increases in quantity, and the whole outlook of the patient returns to a happier state. The digitalised heart is of great interest. The site of maximum stimulation appears to be the auriculo-ventricular node, and this in effect amounts to a partial block to stimuli arriving from the auricles. The normal reciprocal innervation by the sympathetic and vagus is suspended and we have a heart dominated by the vagal side. In other words, the heart is no longer capable of fine adjustment to somatic requirements through sympathetic influence. Complete heart-block means the absolute isolation of the heart from coördinate output of blood in response to the demands of the organs. The digitalised heart behaves differently, in that the depression of the node is not due to interruption of the somatic nerve connexions, but to an excessive vagal action which is inhibitory. In effect the condition resembles a mild degree of heart-block. The analogy between the digitalised heart and one showing complete heart-block is striking. In complete heart-block the pulse-rate is constant and remains so, regardless of whether the body is in exercise or at rest. The output is a constant and is incapable of increase. When the patient exceeds his cardiac capacity insufficiency of the circulation

[2] G. A. Sutherland: Quart. Jour. of Med., 1919, xii., 183.
[3] G Bourne: THE LANCET, 1926, ii., 491.

becomes apparent. If exercise is carried further, blood accumulates in the muscles in action, the brain becomes anæmic, and he falls unconscious. As a rule these patients are well aware of their cardiac capacity and take no liberties. To a mild degree similar conditions obtain in the digitalised heart. The normal increase of rate in response to exercise is present only to a slight degree. In the normal subject the act of swallowing slightly slows the heart-rate. Under digitalis and in complete heart-block this action is absent.

Toxicity.

Toxicity arises from excessive stimulation of the vagus. The ideal action of the drug is obtained when the cardiac branch alone is stimulated. Drowsiness, headache, nausea, vomiting, and diarrhœa may occur —actions which are all attributable to stimulation of the other branches. Any of these symptoms preclude the further use of the drug for the time being. One dose too much may turn success into failure, hence the importance of rigid supervision of the administration. In the majority of reported cases, which have died under the influence of digitalis, either the drug has been continued in full doses after the slowing effect was obtained or the case showed a slow pulse prior to treatment. With our fuller knowledge and appreciation of the nature of the action of the drug such fatalities should be extremely rare.

Indications for Digitalis.

Heart failure with a slow pulse is not uncommon, but it is a combination which is almost invariably fatal and beyond the aid of any drug. Apart from sudden death—e.g., from heart-block—progressive heart failure is always myocardial in origin. When the circulation begins to fail, the needs of the various organs become clamorous. The dire necessity in each organ for a greater turnover of blood makes itself known to the heart through the sympathetic fibres and the rate increases. The ultimate appeal is to the myocardium. If the latter is so degenerate that no response by increase of rate occurs, the outlook is hopeless from the outset, and it is obvious that no benefit can be derived from further slowing of the heart. The ideal drug in such a case would be one possessing an action of augmenting the strength of the heart-beat. Unfortunately, there is no proof that we possess a drug with a direct action on the strength of myocardial contraction. More commonly, however, the call for more blood is met by an increased rate of heart action. As a rule the increase in rate precedes the signs of failure, and it is the continuance of this rate which leads to exhaustion of the myocardium. The increased rate decreases the efficiency of heart-beat by shortening the period of recovery or renewal of energy in the cell. The rôle of digitalis in such a case is to isolate the heart from the influence of the sympathetic by increasing the influence of the vagus, which acts as a depressor. The result is a slowing of the heart and a lengthening of the diastolic or recovery period. Such a heart is to all intents beating to supply its own circulation, and this is mainly diastolic. The insistent calls through the sympathetic from the various organs are ignored. Slow powerful beats replace the weak rapid ones, the output is augmented considerably, and gradually the whole body recovers. Myocardial rest is the fundamental principle in this process of recovery. When heart failure is accompanied by increased metabolism, as in a fever, the slowing effect of digitalis is seldom obtained, the drug action being too weak to counteract the excessive sympathetic stimuli.

Rapid Afebrile Rheumatic Hearts.—As already stated, an increase of rate in most cases precedes the signs of failure of the circulation. An appreciation of this fact has led to the employment of digitalis in the early stages to preclude the failure which must inevitably follow a prolonged rapid action. Such an opportunity arises in the afebrile rapid heart of rheumatic infection. It is therefore a rational procedure to place such a heart under digitalis and to maintain this effect till the myocardium has recovered its tone and the rate has returned to normal.

The Tachycardias.—In true tachycardias—e.g., paroxysmal tachycardia and auricular flutter—it must be admitted that the action of digitalis is by no means constant, nor are the results reliable. Occasionally it will be found that slowing action is obtained; in others it fails completely or induces irregularities such as auricular fibrillation. The varying results are but expressions of the fact that the conditions are little understood. The inconstancy of the results of administration of the drug appear to indicate that the causes of these tachycardias differ and the sites of origin vary in individual cases. The drug should be tried in full doses, but in the present state of our knowledge the procedure must remain empirical.

Auricular Fibrillation.—The association of digitalis with auricular fibrillation is so familiar that at times it is forgotten that the drug does not cure by any direct action. Failure to secure the desired effect arises from neglect of this fact. The successful cases are those where the fibrillation is accompanied by a rapid heart action, and the converse is equally true; unsuccessful cases are those where fibrillation is accompanied by a slow pulse. The latter cases are more chronic as a rule, the bradycardia being due to myocardial degeneration in most instances. Given a suitable case—i.e., one with a rapid heart-rate—success should be the rule if the drug is administered correctly. A common source of failure lies in insufficient dosage; more failures are due to this than to overdosage. With adequate supervision digitalisation is practically free from danger.

Digitalis has been found of great practical use as an adjunct to quinidine therapy.[4] Quinidine is the only drug known which possesses a direct action on auricular fibrillation. In some 50 per cent. of cases of fibrillation it is comparatively easy to re-establish the normal sinus-rhythm, but to maintain this state for sufficient length of time to confer a real benefit on the patient is another matter. As a rule a relapse occurs in a very short time and the patient is in statu quo ante. The reason for this in many cases is to be found in the rate of the pulse, which is often considerably increased, and some degree of myocardial exhaustion is probably a factor in the return of fibrillation. Experience has shown that digitalis is much superior to quinidine in maintaining the normal rhythm after it has been re-established. In many cases the quinidine treatment has to be abandoned owing to the onset of ventricular tachycardia. The pulse-rate suddenly increases to about 160 beats a minute, and this is accompanied by much apprehension and discomfort. Further administration of the drug may lead to death from circulatory inefficiency. It is this unfortunate feature of quinidine therapy that has led many physicians to discard the drug entirely. Recently in America,[4] it has been shown that this tachycardia can be eliminated by first digitalising the heart and then proceeding to quinidine. The procedure in this combined treatment can be conveniently described in three stages. The first, stage begins with the digitalisation of the heart. This may in itself indirectly cause a return of the normal rhythm, thus eliminating the necessity for quinidine. The next stage begins within a day of the slowing of the pulse-rate, which should not exceed 80 beats per minute. Quinidine sulphate is now administered at regular intervals until the pulse becomes regular. When this object has been attained, digitalis is again given in sufficient quantity to ensure a steady pulse between 70–80 beats per minute. The maintenance dose should be continued indefinitely. The results of the combined treatment are decidedly better than those of quinidine alone, and my own experience of this dual method has been very encouraging. The administration of quinidine requires a careful study of the individual patient as well as a knowledge of cinchonism before it can be used with safety.

CHRONIC APPENDICITIS IN CHILDREN.*

By A. J. WALTON, M.S. Lond., F.R.C.S. Eng.,
SURGEON TO THE LONDON HOSPITAL.

Not long ago I produced evidence [1] to show that in adults chronic appendicitis rarely occurs as a primary disease, and is generally the result of an acute attack, most so-called cases of chronic appendicitis being in reality atonic conditions of the cæcum associated with virginal ptosis. If these views were correct, one would expect to find that chronic appendicitis is much less frequently diagnosed in young children, for before the age of puberty there is but little difference in the build of the two sexes, and the changes of virginal ptosis have hardly become evident. It is true, as I have previously shown,[2] that occasionally young girls with ptosis will present symptoms somewhat closely resembling acute appendicitis, but such cases are relatively uncommon. Also, if this were a correct explanation it would account for the fact that I had found—I believe in common with most surgeons—so few cases of this variety in my series.

It is my custom to classify and index all my appendix cases as "acute" and "chronic." In the former group I include all gangrenous, perforated and acutely inflamed cases, while in the latter I include those with no active symptoms, even if they have followed late after an acute attack, those with distension, fibrosis, stricture-formation or external dense adhesions. Probably it includes a certain number in which the appendix was not really diseased but showed senile atrophy, or was involved in a Jackson's membrane due to a virginal ptosis. Of cases of appendicitis uncomplicated with other lesions there were 906 examples. Of these, 601 were classified as acute and 305 as chronic. Of the acute, 310 were males and 291 females, giving 50·8 per cent. males; very nearly an equal ratio. In the chronic there were 147 males and 158 females, giving 48·1 per cent. males, again very nearly the same frequency; but it is interesting to note that since visceroptosis has been recognised as a clinical entity, appendices only bound down by Jackson's membrane have not been included in the series of chronic cases. If I had included with this latter group 451 examples of visceroptosis which showed approximately an 80 per cent. frequency in females, the proportion of males in this group would have been approximately only 31 per cent. The difference is, however, seen most markedly when we investigate the frequency with which these two varieties of disease affect young children. I have divided these cases again into two groups, those over and those under the age of 14. In the acute group, of 601 cases there were 186 patients under 14, 106 of them being males and 80 females. This gives a percentage of 30·9 in children under 14. In the chronic group, of 305 cases there were, however, only 33 cases in children under 14; 17 of them were females and 16 males, thus giving a total of 10·8 per cent. When, however, we come to more closely investigate these 33 cases which are classified as chronic appendicitis, further points of very considerable interest emerge.

The cases were of the following varieties:—

1. *Following acute attacks.*—There were 17 cases where the operation followed a few weeks or, at most, a month or two after a definite acute attack which had subsided with careful medical treatment. In all, the attacks had been quite typical. In some, an abscess even had been drained, and in all very definite subacute inflammatory changes were found in the appendix. These cases, therefore, should more correctly have been included with the acute group and not among the chronic. They will thus alter the figures, so that of 618 acute cases 203, or 32·8 per cent., occurred in children, and of 288 chronic cases 16, or 5·5 per cent., alone occurred in children. They are, however, a very important group from a practical point of view, for if the assumption is correct that appendicitis in adults or in children practically always commences with an acute attack, it becomes of very great importance to recognise that such attacks are alarmingly frequent in young children, and that acute appendicitis still has a very high mortality among them in spite of the efforts of modern surgery. In children, also, it is a matter of very considerable difficulty to obtain an accurate history of such past attacks, and hence any short illness which is associated with severe pain and vomiting should be regarded with grave suspicion, more especially if it be followed by localised signs of appendicular trouble. I believe one of the most important factors in making a diagnosis of this condition is the fact that these attacks have been rare, or that there has been only one isolated instance. If the attacks have been very frequent I should be very dubious whether the pain was appendicular, for it is very difficult to believe, and my figures would support this view, that a patient could have ten or twenty attacks without perforation and a general or localised pus formation.

2. *Cases with enlarged mesenteric glands.*—There were in this group five cases where the only lesion found was a subacute or chronic inflammatory change in the mesenteric glands, and especially in those glands of the ileo-colic angle. The clinical importance of this condition in giving rise to symptoms which may closely resemble those of appendicitis has been discussed by Carson,[3] and more recently by McFadden.[4] Braithwaite [5] has laid stress upon the fact that the disease may be found in both adults and children, and that in the latter the symptoms may resemble either acute or chronic appendicitis. In the majority of my five chronic cases, the symptoms consisted of short, sharp attacks, often colicky in nature, although there was sometimes dull, aching pain in addition. The nature and source of the infection in these cases is doubtful, but the majority of investigators appear to hold the view that the glands are tuberculous, and that the source of infection is in the lower ileum. McFadden[4] believes that these glands are not enlarged in acute appendicitis. This has not been my experience, for in many cases of acute infection I have found them enlarged and inflamed. In the five cases, however, in this group the appendix was removed in all, but no pathological change was seen. If it be true that the change in the glands is tuberculous, the presence of an apparently healthy appendix would, of course, not absolutely eliminate it as the source of infection, for it is well known that tuberculous changes may occur in the cervical glands; and the tonsils, which are almost certainly the source of infection, may show either no change or only the presence of a few tubercle bacilli. Although the general belief is that these glands are tuberculous, and many of them are definitely proved to be so by pathological investigation, it is not certain that this is the invariable change, and, indeed, clinical evidence somewhat supports the opposite, for not uncommonly only one gland is found to be affected, and there is no evidence of tubercle elsewhere in the body. Whatever be the nature of the source of the infection, my opinion very strongly agrees with that of Braithwaite, that the appendix should always be removed, for even if not the source of infection, all doubt as to the presence of acute appendicitis will be removed in the event of another acute attack. It is, however, to be remembered that with such treatment the symptoms may not be cured, and after a short interval of freedom the attacks may recur as before. McFadden, in his figures, found that only 42 per cent. of cases were cured by appendicectomy, and, as he rightly says, it is doubtful whether all these were cured, as some were only followed for a period of six months.

3. *Cases of visceroptosis.*—There were five cases in young girls of 13 who had suffered from frequent

* Being a paper read at a joint meeting of the Section of Surgery and the Section for the Study of Disease in Children of the Royal Society of Medicine on Feb. 24th. (See THE LANCET, March 3rd, pp. 444 and 453.)

attacks of pain in the right iliac fossa and lower abdomen. They were all characterised by the fact that there had been a large number of attacks lasting only for a few days, associated with vomiting and pain, and in some cases even with pyrexia, but the condition did not progress. The last attack was in no sense more severe than the earlier ones, and although the attacks were frequent there was never any evidence of local tumour formation, although deep and superficial tenderness were often present. After removal of the appendix and division of the membranes and bands, the symptoms were for a time relieved, but they returned again later. In one case which clinically appeared to have been a typical example of chronic appendicitis with a year's history of frequent attacks, there was complete freedom for 16 months after the operation, but the symptoms then returned. This variety is not likely to give rise to so much difficulty in the diagnosis if it be remembered that it is only common in young girls, and even in them is rarely seen before the age of puberty. The important diagnostic points are the frequency of the attacks without progress and the absence of any inflammatory mass, even if an attack had persisted for some four or five days.

4. *Threadworms.*—There were four cases in which there had been mild attacks suggestive of appendicitis and in which, at operation, the appendix appeared to be slightly inflamed. In every case it was removed, and on section many threadworms were found within its lumen. After operation the symptoms ceased, and, although it is difficult to be certain that the presence of the worms could be held accountable for the symptoms, it seems permissible to believe that they might cause local inflammation and even absorption from the appendicular wall. Cases have been reported by other surgeons in which a segment of a tapeworm has been found in the appendix, but in my own group no parasite other than the threadworm has been discovered.

5. In two cases of the group no pathological lesion of any sort was found, but the patients remained well after operation, and it is probable, therefore, that some intestinal upset of a relatively transient nature had given rise to an erroneous diagnosis, and that the medical treatment, which of necessity had followed the operation, had led to a cure of the symptoms.

Conclusions.

An investigation of these figures shows, therefore, that acute appendicitis is an extremely common disease in children, patients under the age of 14 forming a high percentage of all cases affected with acute changes, nearly 33 per cent. of the total occurring in children. It is well recognised that this disease in children has a higher mortality and is more serious even in adults. This may be due to the fact that young children are less likely to notice their earlier symptoms, and that being prone to ill-defined stomach-aches the attack may be overlooked until it has reached a dangerous stage. Whatever be the reason, there can be no doubt that it is of the utmost importance to recognise these attacks and to carry out an operation at the earliest opportunity.

My own cases failed to reveal a single case of appendicitis chronic from the beginning, unless we consider as such those where threadworms were present in the lumen, and I am therefore left with the opinion that such a condition does not exist. The recognition of this fact is as important in children as it is in adults, but for a very different reason. In adults the majority of conditions diagnosed as "chronic appendicitis" are examples of visceroptosis, and the patients ought not to have their appendix removed, for they may not only receive no benefit, but their progress may be adversely affected. Indeed, they may be started upon a course of many abdominal operations. In children, on the other hand, the majority of patients diagnosed as chronic appendicitis are in reality suffering with acute lesions of this or some other viscus and ought to be operated upon without delay, and since acute appendicitis i in them so common and dangerous a condition, a cases of doubt should be operated upon rather tha a tragedy be allowed to occur from neglecting an earl case of acute inflammation. Many a child's lif might have been saved if its appendix had bee removed on suspicion.

THE LATE RESULTS OF PULMONARY FIBROSIS.

By W. BURTON WOOD, M.D. Camb., M.R.C.P. Lond.,
PHYSICIAN TO OUT-PATIENTS, CITY OF LONDON HOSPITAL FO DISEASES OF THE HEART AND LUNGS, VICTORIA PARK, LONDON, E.

The chronic pulmonary catarrhs of childhoo form a pathological rubbish heap comparable to th "eczema" of the dermatologist and the "function neurosis" of the neurologist. Thus the term "fibroi lung" is often loosely applied to a variety of cond tions ranging from chronic catarrh to bronchiectasi the child "with a weak chest" and the victim one of the most horrible of all diseases being place in the same category. The need for determining th relationship between the various forms of pulmonar fibrosis is apparent when we consider the clai of the surgeons that timely operation on earl bronchiectasis may avert the tragedy of its grav manifestations.

Bronchiectasis is usually regarded as a diseas It should be recognised not as a disease in itself bu as the late result of an inflammatory process. The can be no early case of bronchiectasis. We do n speak of early phthisis with cavitation. In bot phthisis and bronchiectasis inflammation, degener tion, and ulceration must precede the formation cavities. Bronchiectasis may develop rapidly, as i the case quoted by Osler in which well-marke dilatation of the bronchial tubes was demonstrate at autopsy six weeks after the onset of an attack broncho-pneumonia. In cases of this kind preventiv treatment is obviously impossible, but such cas are rare. Can we anticipate the occurrence of bro chiectasis in those cases of chronic interstitial inflan mation of the lungs which form so large a proportio of the number of patients attending the out-patien clinics of urban hospitals? Is there any distinctiv type of pulmonary infection of this kind which ca be recognised as the precursor of bronchiectasis?

The chronic pulmonary catarrhs of childhood ma be classified according to the extent of symptoms an physical signs. For practical purposes four grou may be recognised.

(1) *Chronic Pulmonary Catarrh.*—This group i cludes those cases in which an obstinate catarr usually confined to the lung bases, suggests tha there is some permanent fibrosis. Though the sig clear at intervals they have a tendency to recur.

(2) *Pulmonary Fibrosis.*—These cases are simil to those of group 1, but the catarrhal signs nev entirely disappear, are usually limited to the lun bases, and vary in extent and intensity from time t time. Some impairment of the percussion note usually evident. Definite clubbing is seldom see but the skin over the dorsal aspect of the termin phalanx, above the nail root, is usually slightly raise pink and shiny. A measure of permanent fibrosis the lung has probably occurred.

(3) *Fibroid Lung.*—In this group are included those cases of pulmonary fibrosis in which the increase in fibrous tissue is so great that the physical signs are those of solid lung. Breath sounds heard over the implicated area are weak and crepitations less evident than in group 2. Pleural effusion or pneumonia is often suspected. Contraction of the chest wall and cardiac displacement are accompanied by dyspnœa. Expectoration of sputum is the rule, even in quite young children. Clubbing is usually evident.

(4) *Bronchiectasis.*—In this group the signs and symptoms of bronchial dilatation or basal cavities are added to those present in group 3. The sputum is copious and fœtid, and hæmoptysis is common.

Is the condition noted in cases in group 1 an early stage of that found in group 2? In particular, will the sufferers from fibroid lung included in group 3 ultimately develop bronchiectasis? With a view to answering these questions an attempt has been made to trace the after-histories of children of 14 years of age and under who were admitted to the Victoria Park Hospital during the decennial period 1905–14 with the diagnosis of "fibroid lung." Out of a total of 167 cases 26 were traced. Of these 13 responded to an invitation to attend at the hospital, letters were received from 5, information was obtained by inquiry in 2 cases, and the death of 6 was ascertained.

The "admission period" chosen ensured that the survivors should have reached adult age, a minimum period of 13 years having lapsed since the date of discharge from hospital. The diagnosis at the time of admission had been fibroid lung, pulmonary fibrosis, or bronchiectasis. A careful study of the ward notes has been made, and from the condition on admission, the course of the disease while the patient was in hospital, and the condition on discharge, the cases have been allocated to the four groups described above. The cases have been reclassified according to their present condition as ascertained by recent examination, or by news lately received, and the deaths have been noted. The result as set out below does not pretend to scientific accuracy, but may serve as a guide to prognosis. It may also tend to qualify the zeal of those who, in a laudable desire "to do something," overlook the fact that a bad prognosis is not inevitable. It will be noted that in no instance has a case originally classed in group 2 deteriorated to group 3. Group 3 yields 2 deaths, and 2 apparent recoveries, while 2 patients are still alive and fairly well despite well-marked signs of fibroid lung, their present age being 28 and 31 years respectively. Of the 2 cases originally belonging to group 4 one has improved and is now placed in group 3, while one has died.

Summary of Cases.

In the following table the grouping is based on the condition of the patient at the time of discharge from hospital. The comment refers to the patient's present condition or death:—

Group 1.

Case.	Original distribution.	Redistribution as determined by present state.
(q)	..	Recovery.
(d)	..	Subject to winter coughs.
(m)	..	Recovery.
(p)	..	"
(r)	..	"
(v)	..	"

Group 2.

Case.	Original distribution.	Redistribution as determined by present state.
(a)	..	Group 2.
(e)	..	Recovery.
(f)	..	Group 2.
(l)	..	Recovery.
(m)	..	Group 2.
(t)	..	"
(u)	..	Recovery.
(z)	..	Group 2.

Group 3.

Case.	Original distribution.	Redistribution as determined by present state.
(b)	..	Group 2.
(c)	..	" 3.
(h)	..	Recovery.
(i)	..	"
(j)	..	Group 3.
(k)	..	Died. (Death attributed to pulmonary tuberculosis.)
(s)	..	Died.
(x)	..	"
(y)	..	"

Group 4.

Case.	Original distribution.	Redistribution as determined by present state.
(g)	..	Group 3.
(o)	..	Died.

Case (w) died of pulmonary tuberculosis which was probably the cause of the original catarrh.

Conclusions.

Opinions based upon a limited number of cases and upon histories which are incomplete cannot be accepted as final. The results of the present investigations suggest that (*a*) a diagnosis of post-pneumonic fibrosis is only justified when the physical signs of this condition are definite and persist over a period of some months. (*b*) When permanent fibrosis of a lung results from broncho-pneumonia, bronchiectasis is not an inevitable sequela. (*c*) Fibroid lung is compatible with fair health over a period of many years, provided that it is not associated with bronchiectasis. (*d*) These records, admittedly incomplete, support the general opinion that the prognosis of bronchiectasis in childhood is always grave and death before adult life is to be anticipated.

Note.—Since the completion of the above three more cases have been traced. One of these would fall into Group 2 and two into Group 3. Over 20 years have elapsed since one of the latter, a man now aged 31 years, was discharged from hospital. Despite a massive fibrosis of the left lung and extreme contraction of the chest wall he has worked as a docker during the last 12 years. He states that he remains free from any chest symptoms except for occasional slight cough.

MEDICAL DIATHERMY IN CHRONIC MIDDLE-EAR DEAFNESS.

By DAN McKENZIE, M.D. Glasg., F.R.C.S. Edin.,
SURGEON, CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, ETC.

A RECENT experimental trial of medical diathermy in chronic catarrh of the middle ear has so much diminished the deafness and tinnitus that I draw attention to the method in order that others may try it. In this form of diathermy a beam of high-frequency current traverses the tissues between two electrodes and raises their temperature. It is solely to the rise in temperature that the therapeutic action of the remedy is attributed. For detailed information on diathermy, both medical and surgical, the reader is referred to Dr. Cumberbatch's book.[1]

Several methods of application to the ear have been proposed and carried out, but the following is that which I prefer, for reasons given later.

Method of Application Described.

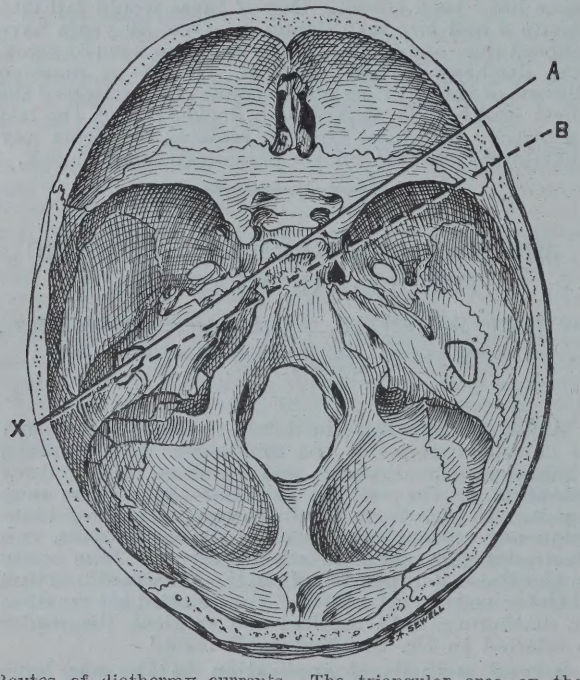
The electrodes used are made of metal, and are of the same size, their superficial measurements being 1 inch by 1½ inches. One is placed over the mastoid process, and the other is laid upon the face just below the prominence of the malar bone, or a little behind it. The position of the face electrode varies according to the shape of the head and that of the mastoid, the aim being to bring the two electrodes as nearly as possible into parallel planes. When I first began to use the diathermy current in ear disease I placed the ear electrode upon the auricle, but it was found that, in spite of careful padding, the irregular surface of the pinna made it liable to burns. The mastoid was therefore chosen. A pad of several layers of lint, thoroughly soaked in 10 per cent. saline solution, is interposed between each electrode and the skin. The patient should be lying down on a comfortable couch, and the electrodes may be strapped on with a rubber band and kept in position with suitable sand-bags, but whatever method be adopted the contact must be close, or sparking will occur and the skin may be burned. The current we use varies from 0·7 to 1·4 amp., according to the patient's feelings (and according also to the amperemeter, for these instruments show variations in their readings). It is gradually raised from zero up to the point when the patient begins to feel the skin under one or other electrode becoming too hot; the strength of the current is then gradually reduced until the point of tolerance is reached, and it is kept there for from seven to ten minutes. After the current is shut off the patient should remain recumbent for a few minutes, as

[1] Diathermy. By Elkin P. Cumberbatch, London, 1927.

vertigo is sometimes experienced if he assumes the erect posture too quickly. The treatment should be repeated every other day. As a rule, I find that, if benefit is going to be received, the patient will become aware of an improvement in symptoms before the end of the second or third week. The treatment is painless if care be taken not to overheat the skin, but as this may occur unexpectedly a trained attendant should be at hand to regulate the current when necessary.

The application may be followed by a reactionary dulling of the hearing for 18 to 36 hours, but many patients fail to experience any reaction. An increase in loudness of the tinnitus may also be observed and may persist longer than the period of dull hearing.

With the electrodes in the positions described above, the current occupies the mastoid process, the middle ear and cochlea, the petrous bone and the Eustachian tube; then it crosses the middle line by the body of the sphenoid to pass by way of the floor of the orbit, the lesser wing of the sphenoid, and the body of the superior maxilla to the cheek (see figure).



Routes of diathermy currents. The triangular area on the petrous represents the tympanic cavity. The lines indicate the main direction of the current ascending to the position of the face electrode, but the current occupies a much wider tract than the lines represent.

After a current of 1·2 amps. had been passing for ten minutes, the temperature under the tongue and outside the region of the "beam" was 99·8° F.

(Current = 0·8 amp.) In the track of the "beam" in the mouth. Temp. = 98·4° F.

(Current = 1·2 amps.) In the mouth as before. Temp. = 100·2° F.

In the external auditory meatus close to the tympanic membrane. Temp. = 100° F.

Indications and Contra-indications.

The region of the current includes the areas which are implicated in tubo-tympanic catarrh, and one would therefore expect diathermy to be most serviceable in that class of case; the expectation generally seems to be realised. Again, in the deafness that lingers after an attack of acute suppuration of the middle ear, when the active disease has subsided, diathermy will be of service. On the other hand, in insular osteoporosis of the labyrinth, or what goes clinically by the name of "otosclerosis," one would scarcely anticipate any benefit from diathermy. Inasmuch as this disease in its pathological appearances resembles rheumatoid arthritis, for which medical diathermy has been used with considerable benefit, we ought perhaps in all cases to make a prolonged trial of the new remedy before deciding against it, particularly in those cases in which the diagnosis of otosclerosis is not quite definite. I can promise some agreeable surprises.

Generally speaking, the presence of pus, or at least an unopened abscess, is regarded as a contra-indication to the use of diathermy. For that reason it should not be employed in acute suppuration of the middle ear, if the membrane is still intact. It is also contra-indicated when hæmorrhage is proceeding or threatening, and so one would hesitate to use it in patients with the Ménière syndrome. Nevertheless, French writers claim successful results even in this variety of ear disease.

Results.

In favourable cases improvement in the hearing and diminution of the tinnitus takes place, and in one or two cases under my care the change in the hearing has occurred unexpectedly. In one instance, that of a medical man with increasing deafness of ten years' standing, the hearing for the tuning-fork at the meatus rose from minus 20 seconds to minus 10 seconds after the fourth exposure to the current, and the improvement continues. The effect on tinnitus has proved also to be full of surprises. In some it has at once become much less loud; and one patient lost her noises altogether. In others an unusual fluctuation in the intensity of the tinnitus was noticed; at one time it would become louder than ever, at another it would be so soft as to be scarcely audible. But the tendency in these cases also has been for the noises to become, as time has gone on, more and more subdued. When it is remembered how intractable tinnitus has proved to all former methods of treatment, this result will bring a sense of hope to all otologists and their patients. At the same time the diathermy made, or seemed to make, the tinnitus much worse in one of our patients. One must therefore be guided by results.

For how long a time the treatment should be continued also depends largely upon results. Thus in early, mild cases a few weeks of treatment will be sufficient, whereas we can scarcely expect to relieve old obstinate cases of middle-ear deafness for many weeks or even months. French workers [2] apply the current daily for two or three weeks at a time and then stop. They also use the semi-vacuum glass electrodes inserting them into the external auditory meatus. The risk of burning the canal and perhaps also the tympanic membrane has hitherto deterred me from trying this route of application.

It will be gathered from what I have said, and I wish to emphasise the point, that the treatment is still in the experimental stage, but my experience of it has already been so unexpectedly favourable that I have no hesitation in recommending it to the attention of otologists as by far the most promising of all the recent plans proposed for the alleviation of "dry deafness."

BRISTOL GENERAL HOSPITAL.—At 3.30 P.M., on Friday, March 30th, Sir Thomas Horder will open the University centre of cardiac research. Tea will be served in the nurses' lounge.

LEEDS SCHOOL OF DENTISTRY.—Mr. J. H. Whitley, M.P., Speaker of the House of Commons, on March 16th opened the new dental school and hospital which has been erected at a cost of £45,000 on a site adjacent to the Leeds Medical School and the General Infirmary. The site, valued at £8000, was provided by the General Infirmary authorities, and towards the total cost £6500 was contributed by the Dental Board of the United Kingdom and £2600 by the honorary staff of the school. It will provide accommodation for 150 pupils and students. To mark the occasion the University of Leeds conferred the honorary degrees of Doctor of Philosophy on Mr. Charles Rippon, president of the British Dental Association, and of Master of Science on Mr. W. S. Thorburn, warden of the Leeds School of Dentistry and Mr. Walter Marston, chairman of the clinical dental committee of the University.

A NOTE ON THE PATHOLOGY OF EPIDEMIC CATARRHAL JAUNDICE.

By E. ATHOLE ROSS, M.D. Camb., M.R.C.P. Lond.,
CLINICAL PATHOLOGIST, ROYAL HANTS COUNTY HOSPITAL, WINCHESTER.

Epidemic catarrhal jaundice has lately been the subject of a report from the Ministry of Health,[1] and recent experience of epidemics in various parts of the country show that the disease is becoming more prevalent, although it has now been recognised in small outbreaks for many years. The following brief pathological note on some twenty cases which occurred in a public school is in no sense complete. It is published merely in the hope that it may be of some assistance to those engaged in future research on the ætiology of this disease. Since writing it I have received a private communication from Dr. Bruce Young, in which he advocates isolation of the patients and disinfection of their excreta, while Dr. C. B. Fuller informs me that he has attended one or two families in which nearly every member fell a victim to the disorder.

The cause of epidemic catarrhal jaundice remains obscure. Weil's disease (icterohæmorrhagic jaundice) is known to be due to the leptospira icterohæmorrhagiæ, and is a serious epidemic disease, while epidemic catarrhal jaundice is not dangerous. In 1923 Buchanan and Gulland recovered the leptospira icterohæmorrhagiæ from the blood and urine of some miners working in East Lothian, but their success has not been repeated by investigators of subsequent outbreaks. Weil's disease is transmitted by rats, which harbour the leptospira icterohæmorrhagiæ in their kidneys, and which convey the infection by contaminating food with their excreta. In the recent epidemic dealt with in Report No. 42, Major H. C. Brown, of the Wellcome Bureau of Scientific Research, failed to demonstrate a leptospira (except in one case which is open to doubt), in spite of a great quantity of material and very adequate laboratory resources. In view of the failure of so competent an observer to find leptospira it was decided to confine such investigations as could be made here to other possible causes. Sir George Buchanan (Report No. 42, p. 15) says: "I am inclined to the view that such mild jaundice epidemics suggest more a bacterial than a spirochætal infection." He also states that fresh material is being investigated with a view to discovering bacterial infection.

Information as to bacterial infection being a possible cause is at present meagre. The following references are to be found in Report No. 42:—

1. The blood of a child, who appeared to be a typical case, was found to agglutinate *B. paratyphosus* A to 1 in 50 (p. 13).

2. A paratyphoid agglutination test was found negative in five instances in convalescent cases. Two specimens of fæces showed no abnormal bacteria (p. 18).

3. Recently a bacillus (?) *B. asiaticus* (Castellani) was recovered from the urine of a convalescent on four successive occasions (p. 18).

Dr. W. A. Bruce Young, M.O.H. City of Winchester, has had experience at first hand of an outbreak of epidemic catarrhal jaundice which attacked some 50 children. Dr. Young read his paper on Epidemic Catarrhal Jaundice of Children to the local division of the British Medical Association and the Society of Medical Officers of Health in March, 1922. This paper contains a wealth of clinical detail, and the following points emerge:—

1. That November is the month of election for these outbreaks—a curious and unexplained fact. It is noted also that influenza is often very prevalent in November, and the question of connexion between the two diseases naturally arises.

2. That the victims were very generally of tender age and that the title Epidemic Catarrhal Jaundice of Children is justified.

3. That in these epidemics constitutional disturbance is more marked than in ordinary obstructive jaundice.

Following up Dr. Young's experiences it seemed desirable to find by blood examination what degree of constitutional disturbance was present, and also to see if blood examination afforded any indication for paratyphoid agglutination tests on any of the patients. White cell counts and differential blood counts were done on three of the patients, and four complete bacteriological examinations of fæces and one of urine were made. Owing to the common occurrence of nephritis in Weil's disease, the urine of four patients was tested to see if any connexion between epidemic catarrhal jaundice and the more serious disorder could be established.

Results.

(*a*) *Bacteriological examination of the fæces.*—Four patients were examined; all of them were found negative for streptococci, hæmolytic or otherwise. In the fæces of three no abnormal bacilli or other micro-organisms were found. In the fourth patient the findings were abnormal. A paracolon bacillus was isolated in pure culture and very few colonies of the normal *B. coli communis* were present on the plates. There was also a trace of pus and numerous bacilli in the urine, but the organism isolated here was *B. coli communis*.

(*b*) *Blood examinations.*—About 15 boys were treated in the sanatorium, while two or three others in various houses were confined to the house sick-room and not sent in. The matron informs me that at the onset the temperature was about 101° F., and the pulse was slow. In none of the four patients examined did the blood count reveal any marked constitutional disturbance. Only the fourth case showed a slight leucocytosis. This is of interest in view of the presence of abnormal bacilli in the alimentary tract, and of a urinary tract infection at the same time. These findings tally with the clinical observations of the medical officers, who report that none of the patients was seriously ill. These examinations were not in any way suggestive of the infective agent being a bacillus belonging to the typhoid or paratyphoid group, as no leucopenia was observed.

(*c*) In four cases the urine was examined for the presence of albumin and casts. In only one was evidence of a mild nephritis obtained.

Discussion.

1. This epidemic confirms the observation that for some unknown reason outbreaks of epidemic catarrhal jaundice are liable to occur chiefly in or about the month of November.

2. The average age of the patients was about 15 years. In this respect, therefore, the outbreak was not quite similar to the one previously observed.

3. There is present, especially at the onset, the constitutional disturbance to which Dr. Young has drawn attention. The blood examinations, however, seem to indicate that this is of but short duration, nor is the blood picture in any way suggestive of typhoid or paratyphoid infection.

4. In contrast to Weil's disease nephritis is slight or absent. It has happened to me in common with others to isolate an abnormal bacillus from the intestine in one case. It is evident that the only way to settle the question whether epidemic catarrhal jaundice is due to bacterial infection of the intestinal tract would be to make a complete bacteriological investigation of the excreta in every patient concerned. Possibly in some future epidemic the Ministry of Health would place one of their whole-time pathologists at the disposal of the authorities. It is also advisable to extend the search to the anaerobic group. The one or two anaerobic cultivations I undertook showed nothing abnormal. Some pathological investigation was made on more than half of the patients. Doubtless efforts to incriminate a leptospira will continue.

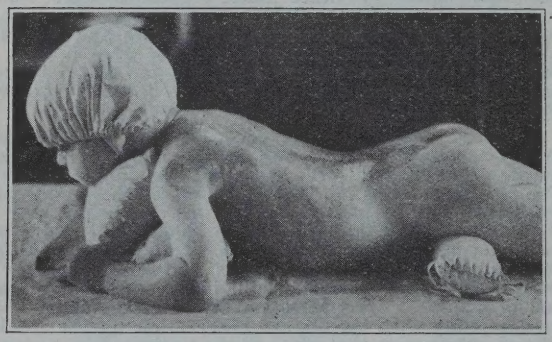
Clinical and Laboratory Notes.

A NOTE ON THE TREATMENT OF TUBERCULOUS DISEASE OF THE SPINE IN YOUNG CHILDREN.

By L. S. Fry, M.B., B.Chir. Camb.,
LATE ASSISTANT MEDICAL OFFICER, QUEEN MARY'S HOSPITAL, CARSHALTON; MEDICAL SUPERINTENDENT, HIGH BEECH HOSPITAL FOR SURGICAL TUBERCULOSIS, ESSEX COUNTY COUNCIL.

The treatment of Pott's disease in children under 3 years of age presents certain difficulties over and above those encountered in the treatment of older children and adults. In infants especially it is often difficult to obtain the necessary immobilisation, owing to frequent movement for nursing purposes and by reason also of their inherent restlessness. The Carshalton frame, mounted on blocks on the bed, meets these difficulties satisfactorily, but it is expensive and has to be made separately to fit each individual, unless a large number of frames is kept in stock. Any satisfactory method of treatment must ensure adequate fixation of the child in the correct position in a comfortable form of apparatus; it should allow of free exposure of the body to the sun and, if possible, permit movement of the legs below the knees. Inasmuch as correction of deformity and reformation of diseased vertebræ is more likely to take place in young than in older children, it becomes of additional importance to provide an efficient form of apparatus. The writer has, for some years, found a plaster bed or boat, extending from the head to just above the knees, the most useful and satisfactory method of treatment in infants. The boat rests on wooden blocks screwed into the plaster and raised high enough above the level of the bed to admit a bed-pan without movement of the child. The raising of the boat has the additional advantage of permitting a considerable amount of movement of the legs.

Fig. 1.

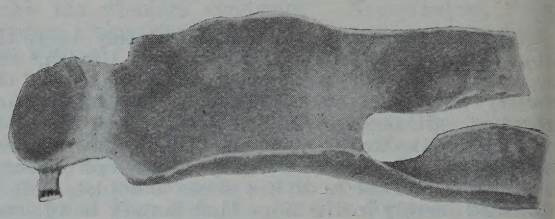


The child in position.

Construction of the Boat.

The child is placed face downwards on a table with a wedge pillow under the chest and chin, and a small pillow under the pelvis if necessary. (Fig. 1.) The spine is thus slightly extended. The legs should be well abducted, as this facilitates subsequent nursing. The boat is then built up with wet plaster bandages, applied in the ordinary way to the previously oiled back of the child. It will generally be found convenient to have in readiness three or four "slabs" made of several thicknesses of folded plaster bandage to reinforce the lumbar and shoulder regions which rest on the blocks. It is important to see that the first layer of bandage is laid on smoothly without wrinkles, as this, of course, forms the inner surface of the boat on which the child lies. The bandages are applied at first transversely to the body and then longitudinally from the head to just above the knees. When the plaster has begun to set, the boat is lifted off the child's back (Fig. 2), a suitable opening

Fig. 2.



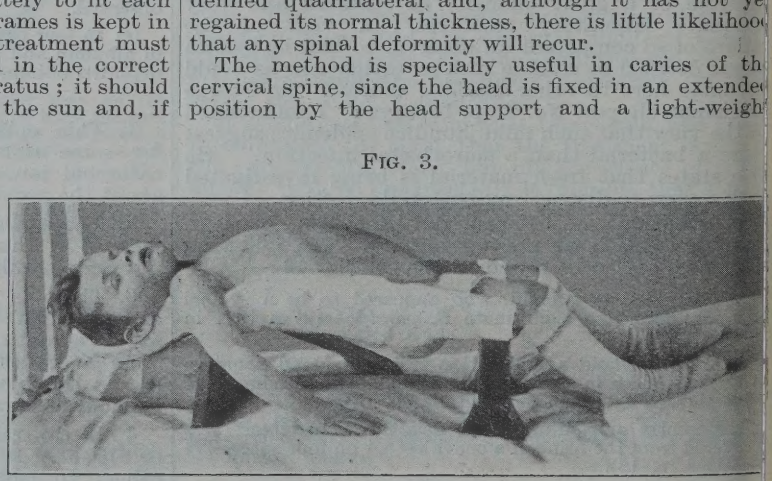
The boat completed and ready to be mounted on blocks of wood.

is cut away in the anal region, and the edges are bound with a single layer of plaster bandage. When dry the inner surface may with advantage be given a coating of celluloid to render it less porous. The boat is then mounted on stout wooden blocks as described (Fig. 3).

In a properly constructed boat the child's spine will be slightly extended, and, if the aim is to "camouflage" the hump by producing compensatory spinal curves, a firm leather pad may be placed just above or below the kyphos as required. Should it be desired to open out the diseased vertebræ still further by hyper-extension, the pad may be placed directly under the apex of the deformity. It is not possible by this method to produce the high degree of hyper-extension effected by the Alton "back door splint" or the "push-and-pull" apparatus, but enough extension can be obtained to allow of re-formation and recalcification of diseased vertebræ. In the case of a child treated as described radiograms taken at an interval of 20 months show that the body of the second lumbar vertebra has re-formed from an indeterminate wedge-shaped mass into a fairly well-defined quadrilateral and, although it has not yet regained its normal thickness, there is little likelihood that any spinal deformity will recur.

The method is specially useful in caries of the cervical spine, since the head is fixed in an extended position by the head support and a light-weight

Fig. 3.



Child lying in the boat.

extension may easily be applied if desired. In practice it is not usually necessary to move the child more often than once or twice a week, and with careful nursing the boat should last for three or four months. Fixation of the spine on a firm, unyielding support is thus secured. Towards the end of the period of recumbent treatment the boat is removed for a part of each day and the child placed on his face to encourage exercise of the back and thigh muscles and to allow the sun to reach the back.

Although no originality is claimed for this method it is suggested that it might perhaps be used more frequently in the treatment of caries in infants.

Summary.

(1) The technique is simple and the material required inexpensive. (2) Fixation of the spine in good position is secured, if the boat is made with the child in the correct posture. (3) The raising of the boat on blocks above the level of the bed simplifies nursing and avoids the necessity of moving the child whenever a bed-pan is used. (4) Children quickly become accustomed to the apparatus, and sore backs are almost unknown.

LOCAL FAT ATROPHY FOLLOWING INSULIN INJECTIONS.

BY E. ARNOLD CARMICHAEL, M.R.C.P. LOND., F.R.C.P. EDIN.,

AND

GEORGE GRAHAM, M.D. CAMB., F.R.C.P. LOND.

INSULIN may cause several forms of local reaction which are now well known. We have recently seen three patients who had a peculiar local atrophy of the subcutaneous fat. This seems to be a very rare condition and has only been reported by three observers, as far as we have been able to ascertain. Barborka [1] reported two cases and Depisch [2] five cases in 1926; Mentzer and DuBray [4] reported several cases in 1927. As the condition has not been described in this country, we thought that a short account of our findings would be of interest.

CASE 1.—A woman, aged 49, who had had diabetes mellitus since July, 1923, was given insulin in September, 1925. The blood-sugar fell to normal with ten units of insulin and her general condition has been very good. She has always given herself the injections in the left arm near the deltoid, and has not obeyed the direction which we give to patients—i.e., to vary the site of injection as much as possible. In April, 1927, she noticed some weakness in the left upper arm, but did not complain of it until August of that year. She said then that she had an aching pain in the left shoulder. On examination the left upper arm appeared much smaller than the right. The skin of the upper arm, just below the level of the insertion of the deltoid, was thin. Over an area of nearly 3 in. by 2 in. the skin could be picked up quite easily and there was an entire absence of subcutaneous fat, so far as could be judged by examination. A large vein was visible in this area; above and below it became buried out of sight in the normal subcutaneous tissue. The surrounding skin and subcutaneous fat appeared normal. There was no weakness of the arm muscles and no analgesia. An X ray examination of the shoulder-joint did not reveal any abnormal changes, although the patient complained of some pain on movement.

CASE 2.—A woman, aged 39, has had a mild form of diabetes ever since 1909. She was given insulin in May, 1924. Her general condition is now good. The blood-sugar is normal on diet and with insulin injections. She had definite local reactions with the English insulin to begin with, and had to have Eli Lilly insulin for a time. Later she was able to take the English insulin without any consequent local swelling. She has always used the skin of the front of the thighs for the injections. In May, 1924, she noticed a depression in the front of the left thigh. In September, 1927, she complained of a local swelling of the right thigh, but nothing abnormal was noticed at that time. In October, 1927, after the first patient had been seen, she was re-examined, and a well-marked depression was found on the front of both thighs. The skin could be picked up quite easily, and as the subcutaneous veins could be seen there was probably no subcutaneous fat present. When the skin was tested with faradic and direct galvanic currents goose skin appeared at once, showing that the skin itself was not seriously affected. No anæsthesia was present and the muscles all seemed strong.

CASE 3.—A boy, aged 8, has had insulin in small doses for two years. For the last three months the dose of insulin has had to be increased from five units up to ten or twelve units twice a day. The skin of the upper arms has been chiefly used for the injections, but also that of the front of the thighs. For the last three weeks a definite wasting of the right arm has been noticed; the skin below the level of the insertion of the deltoid is thin and there is apparently no subcutaneous fat. The muscles are unaffected. On the left side the same condition is present to a slight degree. The boy's mother thinks that the skin of the left arm has already begun to improve since the injections into the arms have stopped.

This condition of atrophy of the subcutaneous tissue may be due either to insulin itself, or to something which has been injected as an antiseptic. At hospital the needles are always kept in a mixture of lysol 1 oz. and methylated spirit 20 oz. in order to prevent rusting. The patients are instructed to wash the syringes out with six changes of cold boiled water. It seemed possible that the atrophy of the fat might be due to the injection of small amounts of lysol. The third patient, however, had never used lysol, as stainless steel needles had always been used and were kept in industrial spirit.

A fair number of patients have now been seen who have suffered considerably from local reactions; in none of these has local atrophy of the fat been observed. Only one of our three patients had any local reaction after the insulin injections. It is, therefore, improbable that the atrophy is connected with any of the usual local reactions. Insulin injections may cause toughness of the skin, so that sharp needles pierce it with difficulty. In the cases of fat atrophy the skin has not been affected in this way. It is also unlikely that it has been caused by involvement of the local nervous mechanism, either somatic or sympathetic. The entire absence of muscle wasting and anæsthesia excludes the somatic nerve, and the presence of the local pilo-motor reflex on faradic stimulation, according to Lewis and Marvin, [3] is in favour of an intact sympathetic system. So far as we are aware, a similar condition has not been reported after the repeated hypodermic injection of any other drugs.

Our observations, together with those by Barborka and Depisch of similar cases after insulin injections, make it almost certain that the condition is directly due to the insulin. It is possible that minute amounts of a fat-splitting ferment are present, as insulin is prepared from the pancreas. In the three cases we have reported, and in those of Barborka, the insulin had been injected too often in one localised area, with the result that changes in the subcutaneous fat have been brought about, presumably by the repeated minute doses of a lipolytic ferment.

The treatment would seem to be the avoidance of the same area of skin for repeated injections. It will be of interest to see if the fat returns, or if the damage is permanent.

DONATIONS AND BEQUESTS.—Mrs. Hannah McCulloch, of Bettwsycoed, left £2000 to the Bettwsycoed War Memorial Institute, and £500 to the Llandudno Cottage Hospital, and the Croesynyd Isolation Hospital.—The late Mr. Russell Allen, of Davenham Hall, Northwich, left £4000 to the Cheadle Royal Lunatic Hospital, Cheadle, Cheshire, £1000 to the Manchester Royal Infirmary, to endow a bed to bear the following inscription: "16th (the Queen's) Lancers Bed, in memory of John Edric Russell Allen"; £500 each to the Manchester Royal Eye Hospital, St. Mary's Hospitals for Women and Children, Manchester, and St. Dunstan's Hostel for Blinded Soldiers and Sailors.—The late Mr. George Chalmers, of Mooro Velho Villa, Nova de Lima, Estado de Minas, Brazil, left to the executors £500 for any institution for research work in cancer and £500 for any institution for research work in consumption.—Mrs. Emma Grace Caird, of Dundee, besides other bequests, left £5000 to the Royal Dundee Institution for the Blind, £20,000 to the Caird Jubilee Nursing Home, Dundee, and £1000 to the Helensbury Infirmary. Subject to other gifts, she left the residue of her property as to one-half to the Dundee Royal Infirmary, the income thereof to be applied for the benefit of that institution and the Sidlaw Sanatorium.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ELECTRO-THERAPEUTICS.

A MEETING of this Section was held on March 16th, Sir HENRY GAUVAIN, the President, in the chair. A paper on the

PRESENT POSITION OF RADIUM THERAPY.

was read by Mr. A. E. HAYWARD PINCH (Director of the Radium Institute). He began by giving a brief account of the use of radium in surgical practice, from the time when, 32 years ago, Becquerel read his historic paper on uranium radiations, followed in 1898 by Madame Curie's discovery of radium. At first, he said, radium was used medically as a mild caustic, then it was enclosed in tubes for the treatment of easily accessible tumours. The results were encouraging, and there was now a very elaborate "surgery of access" for the purpose of treating tumours by irradiation. Prof. G. E. Gask, at St. Bartholomew's Hospital, had recently performed plastic resection of the front of the skull, and introduced a radium "seed" into the pituitary body, and Sir Charles Gordon-Watson did a modified Kraske operation to apply radium to a tumour of the rectum. This use of screened radium emanation seeds was the latest development of technique. The use of unscreened seeds had at one time been advocated, but they had been discarded at the Radium Institute as they caused a good deal of necrotic action and pain, and sepsis was a usual sequel.

The alpha rays of radium, said Mr. Pinch, could be left out of a medical discussion; the important ones were the beta and the gamma rays. 94 per cent. of beta rays were absorbed by 1 cm. depth of body tissues, and these rays were the best for the treatment of superficial lesions. Gamma rays were employed for deep radiation. The screens used at the Radium Institute were the following: 0·01 mm. aluminium when the action desired was on the true epidermis; lead of 0·1 mm. thickness for the upper layers of the corium; and silver 0·5 mm. thick, or for the deeper layers 1 mm. thick. By varying the time of exposure and the strength of the apparatus, any desired results could be attained. He showed slides to illustrate a case of lichenification of the skin in neuro-dermatitis, which was cleared up by radium applications after the patient had undergone nervous shocks. One case of circinate psoriasis he had cleared up by three exposures (on three successive days) each of three minutes' duration, using a flat applicator. There was no recurrence. Psoriasis of the glans penis yielded to radium when all else failed. Cavernous nævus cleared up after three half-hourly exposures on successive days, the treatment being repeated in six months. The screen used was 0·1 mm. of lead. Lupus was treated in the same way as cavernous nævus, but the seances were one and a half to two hours, repeated in six weeks. He showed photographs of a case of very severe facial burns, caused by petrol, which was restored almost to normal by irradiating the face, inch by inch, through 1 mm. of silver. Rodent ulcer, he said, could be divided into three main groups. In the first group—the hypertrophic cystic variety—the lesion rose well above the level of the skin. The second was the flat, superficial, cicatrising kind. The third was the deeply ulcerating form. This last was not as easy to cure as the other two; it was best to apply to them a small dose, unscreened, for one and a half hours. Mycosis fungoides showed a specific reaction to radium; he showed on the screen a case of it which was successfully treated by radium. Exposure was for one and a quarter hours.

Dealing next with gamma radiation specially, Mr. Pinch gave as his definition of deep radium therapy "the treatment of disease by prolonged exposures with radium or radon apparatus so screened as to emit a preponderant hard beta and gamma radiation, or gamma radiation only." The best screen for securing gamma radiation only was 1 mm. of platinum; this cut out all beta radiation, and transmitted 90·5 per cent. of the gamma rays. For large surface applicators, however, platinum was an expensive screening metal, and other metals could be substituted by using an appropriate thickness. For these large applicators lead was the metal used at the Radium Institute. The screening was entirely a physical action. He mentioned that because one doctor objected to screening by lead owing to its toxic action. Deep radiation could be carried out by using external applicators, either tubes or flat. Contact radiation could be employed, or "distance" radiation. The former was the chief method at the institute. For breast cases a square applicator was used, giving an exposure of 30 to 50 hours' duration, and 300 mg. of the radium element was employed, screened through 2 mm. lead. A disadvantage was that the secondary beta radiation, unless absorbed, would irritate the skin a good deal. "Cross-firing" was done to ensure a fairly uniform radiation to all parts of the growth; and it was particularly valuable for mediastinal growths. Distance radiation by radium was carried out a good deal on the continent, but it required a large amount of the salt, owing to the law of inverse squares. "Collar radiation" was used in the case of glands in the neck, with a mould of wax compound 3 cm. thick.

There seemed to be two schools in regard to methods of application: that which favoured using small quantities for a long time, and that which preferred large amounts and a short exposure. The speaker used both methods, as each had its special value according to the kind of case. Such conditions as periosteal sarcoma and splenomegaly responded best to a large dose applied for a short time. The other method was best for slow-growing squamous-celled endothelioma. He had been much impressed by the efficacy of the burying of screened emanation "seeds," as first carried out in America. Much less damage was involved in reaching a growth, and they could be inserted under local anæsthesia. If they happened to be left in situ they did not corrode nor do any harm. This method produced results which were better than he had seen from any other. He showed photographs of several cases which had been treated by radium seeds, including one of Mikulicz's disease.

Mr. Pinch concluded his address with a protest and a prophecy. He was sorry to notice that a section of the medical profession seemed disposed to depreciate the excellent work being done by British radiologists, though pointing with admiration to the work of any foreign practitioner. His prophecy, given after the fullest consideration, was that in the very near future radium would form as much a part of the up-to-date surgeon's armamentarium as the scalpel, and that it would be possible to treat with confidence and success many cases of malignant disease which at present were regarded as inoperable and hopeless.

Discussion.

Dr. EDGAR HAYDON emphasised the importance of taking into consideration the idiosyncrasies of the patient in radium therapy, because of the variable degree of reaction shown by different people. For the tongue he had at first used rather large doses, and nearly all the cases had gone wrong eventually, though the immediate result was good. Very much better results were secured by using needles 6 mm. long, with 4 to 5 mg. radium, these being left in position from five to seven days; if cross-firing was done, the result was miraculous. The same word was applicable to antrum cases, perforation being first done with trocar and cannula. Cases of antral disease had been cured for seven years without recurrence.

Dr. G. W. HILL spoke of his first application of radium to the gullet, which was also the first case in which radium was so applied in this country. Of

over a hundred cases in which he had used the radiation, one-third had lived a year or more, greatly benefited; one-third were relieved by the treatment, and the remainder either were not benefited or were made worse by it. He hoped it would be possible to evolve a technique for embedding radium in the gullet. To exemplify the extended field of radium applications he mentioned that he had used it for fibrotic ear cases, and for chronic middle-ear conditions.

Dr. J. H. WEBSTER considered, in opposition to Mr. Pinch's view, that distance irradiation was valuable for certain conditions; it would be a great gain if a larger quantity of radium could be secured to the Radium Institute. For primary breast cases and supraclavicular and nodular recurrences he got the best results from the use of 0·5 g. at a distance of 6 cm., giving a total exposure of 25 hours. Recurrences did not follow this treatment.

Dr. F. HERNAMAN-JOHNSON expressed his agreement with Mr. Pinch's prophecy. In the country as a whole there was not enough radium, nor, indeed, enough doctors familiar with its proper use. Judicious use of X rays and diathermy enabled conditions to be dealt with which could be treated more speedily by radium. In all methods of radiation treatment the general condition of the patient must never be lost sight of. Sometimes in treating recurrences by radiation the patient seemed to arrive at the end of his response and nothing remained but to send him away, as no more could be done for him. But within the last year he had been sending such cases to be treated by light, and a number of them had improved in a remarkable manner; pain disappeared, and they gained 8 or 9 lb. in weight in two months. Light treatment, properly applied, raised the resistance and made the patient more cheerful.

Dr. G. E. VILVANDRÉ was rather sceptical about the efficacy of X rays in the treatment of cancer. He knew of nothing which gave such good results in cases of epithelioma as radium. He objected to the use of ultra-violet light in carcinoma.

Sir CHARLES GORDON-WATSON said he would have liked to hear more about the surgery of access. He explained his procedure for rectal growths which were not regarded as operable by surgery. The important need was to know the optimal dose for a particular case. A standard case was that of a woman with a very advanced growth in 1925, who was cachectic and very ill. She had 50 mg. inserted for seven days, and the dosage worked out at 8000 milligramme-hours. The reaction was very severe, and for several days death seemed imminent. Then she improved rapidly, and was now apparently well. He always tried to get parallel rays playing through the growth. When a growth was fixed to the base of the bladder there were great difficulties. In women it was an advantage to be able to put the needles through the vagina into the anterior part of the growth. In three recent cases he had passed radium into the growth through an abdominal incision. If the whole growth did not seem to have been removed, he afterwards placed tubes of 50 mg. in the lumen of the rectum.

Dr. M. H. OLDERSHAW suggested that the difference in behaviour according to whether radium was used in large quantity for a short time, or a small quantity for longer exposures was explained by the fact that the cancer cell was especially susceptible to the action of radium during the process of division. Hence it was important to secure uniform irradiation through the tumour at the time when it was rapidly dividing.

Dr. T. P. LINEHAM spoke of the earlier practice at the Radium Institute, remarking that in skilled hands flat applicators were of great service; hospital equipments should include them. He favoured combining X rays and radium. He agreed that people who had ceased to respond to radium often showed great improvement when subjected to ultra-violet light.

The PRESIDENT raised the question of the possible danger of radium applications, referring to the deplorable results of the application of X rays to lupus vulgaris in early days and asking whether comparable dangers were to be anticipated from radium.

Mr. PINCH, in reply, said he had not attempted to insert radium seeds into the œsophagus from the outside, but had done so from inside for post-cricoid growth. He referred to a case of annular carcinoma in the lower part of the rectal ampulla. A 100 mg. tube of radium for 24 hours was ordered. By an error a second 24 hours' dose was given, and very intense proctitis ensued, but the growth absolutely and completely disappeared. He would not give this large dose deliberately.

HARVEIAN SOCIETY.

A MEETING of this Society was held on March 15th at the Paddington Town Hall, London, when Sir WILLIAM WILLCOX delivered the Harveian Lecture on

TOXICOLOGY AND ITS APPLICATION TO MEDICAL PRACTICE.

After outlining the position which toxicology had now attained in relation to medicine, the lecturer classified the diseases associated with the development of toxins in the body. These, he said, were in some cases produced by the entrance into the body of germs from without which by growth produce toxins, as occurred in the pathogenic diseases: here the invading causal organism was sometimes known. Also in recent years the importance had been recognised, in the causation of many pathological conditions, of the production of toxins at some localised focus, which were then distributed through the circulation into far distant parts of the body. In another class of cases we had, he said, impairment of the function of organs important to the body economy either for the excretion of toxic substances or for the regulation of metabolism—for example, the liver, the suprarenal glands, or the pancreas. Hence auto-intoxication, whose study, he said, was still in its infancy, but as our knowledge advanced we should learn much of the causation of disease and of preventive and curative measures.

Toxic Action of Drugs.

Indicating that the therapeutic action of a drug merged insensibly into a toxic action, the dividing line being influenced by idiosyncrasy or variations in tolerance (due to defective function), he described briefly the symptoms which might arise from the indiscreet use of bromides, iodides, the arsenic and belladonna preparations, the salicylates and salicylic acid, opium and quinine, while he reminded his hearers that in the treatment of many diseases at the present time the administration of large doses of drugs possessing powerful therapeutic action was advocated—in many instances the remedies being given intravenously. Summarising the studies of Ehrlich in his search for remedies which should have a selective toxic action on the invading microbe while remaining harmless for the host, he gave a description of toxic symptoms which might be associated with salvarsan and its congeners. He eulogised the mode in which Ehrlich introduced salvarsan to the medical profession as a model of perfection, seeing that it was delayed until after preliminary trials on the human subject and issued with the fullest warning of possible dangers and with the contra-indications to its employment. After an enumeration of powerful remedies which have been exhibited in many tropical diseases, Sir William Willcox discussed the lead treatment for cancer recently introduced by Prof. Blair Bell, which he described as an example of the careful use of a poisonous metal so as to obtain the full therapeutic effect without the production of serious toxic symptoms. He noted as interesting that the effects following the intravenous use of lead under proper control should differ from the toxic results which occur in chronic lead poisoning, where the drug

has been absorbed by the gastro-intestinal tract; in the latter condition the cardiovascular and nervous systems and the kidneys suffered damage from chronic disease, while these sequelæ were not noticeable after the therapeutic use of lead intravenously.

Liver Poisons.

A large portion of the address was taken up by the consideration of liver poisons—that is drugs in which a substantial proportion of the absorbed poison will be found in the liver. In many cases the lecturer considered that the liver might be said to have laid down its life in its endeavour to protect the body from the action of exogenous poisons, such as phosphorus in particular, salvarsan, tetrachlorethane, trinitrotoluene, and chloroform; while the same result might be said to occur in the action of bacterial toxins such as are found in typhoid and paratyphoid fevers, influenza, pneumonia, in streptococcal and protozoal infections, such as accompany syphilis, yellow fever, kala-azar, malaria, and amœbic dysentery. The result of the action of liver poisons gave rise, he said, to the definite symptoms which in an extreme form comprised the condition known as icterus gravis, and he laid stress upon the need for the practitioner to remember the danger accompanying the therapeutic use of drugs having a toxic action on the liver, for the action of these drugs might lead to a progressive atrophic cirrhosis. Before submitting a patient to the therapeutic action of a liver poison, it was advisable to protect the organ three or four hours beforehand by a small meal of glucose—40 to 50 g. with coffee and a little milk—because liver cells when stored with glycogen have an increased resistance to the action of toxic substances; and he made a plea for the employment of old and well-tried remedies whose therapeutic action was thoroughly understood, for definite danger had attended the employment of some of the newer remedies. Even the well-known animal extracts, insulin, pituitary extract, and adrenalin, had to be used with proper precautions, while the same applied to bacterial toxins in the form of vaccines or antigens.

Criminal Poisoning.

The lecturer warned the audience that the greatest caution, tact, and firmness must be displayed where any suspicion is aroused that a patient was the victim of an intended crime; and in illustration of his remarks he adduced the well-known Maybrick, Seddon, and Armstrong cases; while with regard to the laws relating to the sale of poisons he said that as at present framed they did not keep pace with advances in chemistry and pharmacology. Therapeutic remedies and chemical substances of powerful toxic action were being discovered daily, and were not comprised by the existing Schedules of Poisons. If control was to be kept over the sale of poisons, it seemed that some comprehensive scheme must be devised which will include newly discovered substances of toxic action—this subject was being considered by a Departmental Committee.

Treatment.

After comments upon drug addiction and industrial and commercial poisoning, the lecturer concluded with the following brief note upon treatment: "The cardinal principle in the treatment of poisoning should be the removal of the unabsorbed poison without the least delay. If this were always remembered, many lives would be saved. Where a poison has been taken by the mouth—unless it is a powerful corrosive—the stomach should be efficiently washed out as soon as possible so that any remaining poison may be completely removed from that organ; elimination should be promoted by free colon washing and by the administration of aperients. Where a poison has been injected subcutaneously free crucial incision and cupping will often enable some of the poison to be withdrawn and this will be facilitated by placing a ligature round the proximal portion of the limb if an injection has been made into that part of the body. Suitable antidotes should be given *after* removal of the poison has been effected as completely as possible. In the case of poisons producing prolonged coma, easily absorbable foods should be administered by the stomach-tube at suitable intervals so as to maintain the strength of the patient. *Chemical poisons*, if absorbed in dangerous amount, always produced serious damage to the bodily organs."

HUNTERIAN SOCIETY.

A MEETING of this Society was held at Simpson's Restaurant on March 19th, Mr. MORTIMER WOOLF, the President, in the chair. A discussion on

HICCUP

was opened by Dr. ROBERT HUTCHISON, who defined it as a sudden involuntary contraction of the diaphragm when the inrush of air that should follow was prevented by closure of the glottis. The abrupt arrest of inspiration produced the characteristic sound. The louder the noise the less the distress of the patient. The frequency of the spasm was usually about one-quarter or one-fifth that of ordinary respiration. The efferent nerve was the phrenic and the afferents were the vagus, sympathetic and sensory fibres of the phrenic. The centre had formerly been supposed to lie in the respiratory nucleus, but there was now reason to believe that it might be in the cervical cord in the region of origin of the phrenic. Langeron had found lesions at this site in a case of prolonged hiccup in tuberculous meningitis, while Urechia and Mitalescu had found hæmorrhages in the third, fourth, and fifth cervical segments in a case of cancer of the pylorus with prolonged hiccup. Since hiccup might persist through the apnœic periods of Cheyne-Stokes breathing, it was hard to believe that the ordinary respiratory centre was the centre of hiccup.

Hiccup might arise from stimulation of any of the afferent nerves mentioned—e.g., irritation or over-distension of the stomach, very hot or highly spiced food or alcoholic excess. Curiously, however, hiccup was a rare symptom of dyspepsia. The irritation might arise in the peritoneum or diaphragm, and any fever might be complicated by hiccup. Benjamin Ward Richardson—a teetotaller—had suggested that febrile hiccup had been due to the excessive quantities of alcohol formerly given in fevers. Hiccup might also arise centrally, as in encephalitis and uræmia, or be a symptom of hysteria. The most severe forms were the epidemic and the post-operative. The latter was most common after operations on the upper abdomen and the genito-urinary tract. The patients were frequently elderly men and the condition was essentially a "private practice disease." Dr. Hutchison could not recall a single case at the London Hospital in 25 years. Its occurrence was due to irritation of the afferent nerves, but there need not be peritonitis. Hiccup had been known to cease when a drain was removed from the ileum. Küttner had found that the anæsthetic and the position of the patient in bed had no influence on the spasm. It was not easy to give an explanation of the well-known frequency of hiccup after prostatectomy. Marion had described a number of cases in which it came and went with a rise and fall of urea in the blood. He admitted the difficulty of explaining why hiccup was not more often encountered in ordinary cases of uræmia.

Hiccup varied from a trivial, almost ludicrous, complaint to a most distressing complication threatening life by exhaustion. Knuthsen had described a patient who hiccuped for a month, about 480,000 times in all; he also mentioned a gentleman in St. Louis who had obtained a divorce after his wife had hiccuped for 20 years. As a rule the patient recovered. Knuthsen had listed more than 50 treatments for which success had been claimed; the only inference to be drawn was that none of them was much use. In the milder cases the spasms could be stopped by various dodges that arrested the action

of the diaphragm—e.g., holding the breath, sneezing, tickling the nose, or compressing the abdomen. When gastric irritation was the cause alkalis, carminatives, and gastric lavage might succeed. In toxic cases food should be stopped and elimination encouraged by the administration of large quantities of fluid. In severe cases it might be necessary to act on the nerve centres by sedatives like morphia, chloretone, veronal, bromides, the intramuscular injection of 30 minims of ether or even chloroform inhalation. Success had been claimed, less explicably, for benzyl benzoate, pilocarpine, and nitrites. In America the latest method was the administration of carbon dioxide, on the principle of stimulating the respiratory centre so vigorously that it would not respond to the pin-pricks of peripheral irritation. The reflex arc had been interrupted by compressing the phrenics or paralysing them or the lower cervical sympathetic by novocaine injection.

Epidemic Hiccup.

Sir FARQUHAR BUZZARD said that graphic records had shown that there were two spasms in a hiccup; inspiration and closure of the glottis was preceded by a very brief expiratory spasm. Hiccup had acquired increased importance from its somewhat frequent appearance in epidemic form during the last ten years, especially in America. 3000 cases had been seen in the Winnipeg outbreaks of 1919, 1921, and 1924. Adults had been more affected than children, and males more than females, in the proportion of 9 to 1. Little was known of its contagiousness save that, as in encephalitis, it was rare for two members of the same household to be affected. The incubation period appeared to be nine days and second attacks were very rare. The epidemics generally occurred in winter, lasted six to eight weeks, and were often coincident with epidemics of encephalitis. There might be a prodromal period of lassitude, vague pains, headache, epigastric discomfort and perhaps fever, or the onset of paroxysms might be sudden. The patient usually hiccuped between four and twenty times a minute, often for half an hour at a time with half-hour intervals. Remedies were powerless, but the spasms ceased of their own accord in three or four days. There might be no other symptoms, but often there was some vomiting and tenderness of the scalp, and occasionally headache, which persisted for some time. Death was rare. One fatal case had had six days of hiccup followed by fever and somnolence; at post-mortem his cervical cord in the phrenic region showed inflammatory changes like those of epidemic encephalitis. A typical case of epidenic hiccup might develop symptoms of encephalitis or generalised myoclonus. The condition might therefore be regarded as a small fragment of the symptomatic mosaic of epidemic encephalitis. The ætiology of epidemic hiccup was in its infancy, but it had been brought into line in a striking way with the other manifestations of encephalitis. Hiccup might be an initial symptom of encephalitis, but was rare as a sequel. It often appeared as an epidemic in communities over which a wave of encephalitis had recently passed, and might represent the effects of an agent of lower virulence. It was certainly an important question whether epidemic hiccup should not be notifiable.

There was some evidence to show that the medulla rather than the cervical cord was the centre for hiccup. It was an interesting question what was the original purpose for which hiccup was evolved. Was it in very early days a mechanism to prevent forced and deep inspirations while food was about?

Discussion.

A brisk discussion followed and a number of Fellows and visitors related personal and professional experiences of hiccup.—Dr. J. CAMPBELL MCCLURE said that he had always regarded the medulla as the shunt between peripheral and vagal messages. It was for the patients who made no noise that he was most afraid; he had seen patients quietly hiccup for months and then die. It was a most ominous and terrible symptom, which could not be cut short by one moment; the only treatment was to find the cause and remove it.—Dr. F. HOWARD HUMPHRIS spoke of the value of electrical treatment and diathermy.—Dr. C. F. HADFIELD and Dr. R. J. CLAUSEN spoke of hiccup coming on under anæsthesia. The former had tried carbonic acid gas without success.—Dr. A. C. JORDAN suggested that hiccup might be the beginning of vomiting. Cats hiccuped before vomiting and gastric lavage relieved hiccup.—Dr. A. S. CURRIE thought it was analogous to spasmodic sneezing. He had cured a bad case by large doses of hydrocyanic acid.—Dr. J. ALEXANDER described cases of high blood pressure, renal disease, and auricular fibrillation where hiccup had absorbed all the attention, but had disappeared when the underlying condition was treated.—Dr. D. NORRIS described hiccup in severe cases of typhus in Serbia.

The PRESIDENT thought that the cause in upper abdominal post-operative cases was some irritation at the base of the liver. All anæsthetists knew that pelvic operations required particularly deep anæsthesia, and a last resort to stimulate respiration was stretching the anal sphincter; he suggested that the pelvic diaphragm played some part in respiration. The physiology of respiration and the physiology of hiccup were very much bound up together. He had known vinegar in hourly 1 oz. doses act like magic on post-operative hiccup.

Dr. HUTCHISON, in reply, observed that the subject had been "much laboured but little advanced." He thought that the majority of patients with hiccup tended to recover and that the alleged cures were psychotherapeutic or pure coincidence. Those who died would have died in any case.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

A MEETING of this Society was held at Sheffield on Feb. 24th. Dr. LEITH MURRAY, the President, who took the chair, described a case of

Sarcomatous Metaplasia of a Fibroid.

Malignant change in fibroids, he said, had interested him for many years. The literature in general gave its incidence as from 1 to 2 per cent., whilst Eden and Lockyer believed that it was slightly under 1 per cent. But though he had incised, and cut representative sections from, every fibroid that he had ever removed, he had never before come across definite malignant metaplasia occurring within a fibroid. This suggested that there must often be an element of doubt in the diagnosis. Probably the chance of error had been increased by including fibroid polypi, for on four occasions he had seen an œdematous fibroid polypus whose microscopical appearance was rather suggestive of malignancy. Cytological examination and absence of any recurrence had made it certain that the œdema was the cause of this appearance. In most of the recorded cases the symptoms included rapid growth and blood-stained discharge from the uterus. This discharge suggested that the tumour, if it had really begun in a fibroid, had partially escaped therefrom, and there was a loophole of error inasmuch as a uterine sarcoma, arising, say, in the endometrium and close to a fibroid, might penetrate the fibroid. The case to be described showed definite malignancy arising in the centre of a fibroid removed by myomectomy. The malignancy was not suspected until the specimen was incised after operation. A further point of interest lay in the youth of the patient.

A woman, aged 29, married seven years, had one child aged 6. She complained of aching pain in the right side off and on for twelve months; menstruation 5/28, regular and moderate until one month before she came under notice when, four days after an ordinary period, a further and similar period appeared. Examination showed a rounded and enlarged uterus, the fundus being palpable two inches above the symphysis pubis. A diagnosis of fibroid uterus was made, and on Nov. 20th, 1927, a solitary

fibroid weighing 12 oz. was enucleated from the right wall of the uterus at the fundus through an anterior incision. There was at first slight difficulty in defining the capsule anteriorly, but not more so than there was sometimes with myomectomy operations. The uterine cavity was accidentally opened during the enucleation and was sutured. The specimen had the external appearance of an ordinary fibromyoma, but preliminary incision showed in the centre a soft red and pulpy area, completely surrounded by fibromyomatous tissue. There was a complete layer of pale fibroid tissue beyond the central growth, which at no point had reached nearer the capsule than a quarter of an inch. Microscopical examination showed a core of hæmorrhage and necrosed tissue with malignant areas at the periphery. These areas were definitely cellular and appeared to have a vascular relationship.

The President thought the growth might well be called an endo- or peri-thelioma. It resembled very much a specimen described and figured by Leith.[1] The patient, so far, remained well. Ought he to remove the uterus?

Dr. A. A. GEMMELL (Liverpool) brought forward a case illustrating some of the difficulties of deciding what was the origin of the sarcomata seen in fibroids.

The patient was 54 years of age and had not come to the menopause. She had had four children. Menstruation had been excessive for the last 12 years and she had been losing continuously for four months when she came for consultation. The specimen consisted of the uterus and both appendages removed by total hysterectomy. It weighed 2½ lb. and measured on removal 5½ × 4 × 4 in. It was regular in outline with adhesions of omentum to its anterior surface. The uterus had been opened anteriorly and showed a tumour projecting from the posterior surface and filling the cavity. The lower pole of the tumour was necrotic and had burst. On section the tumour was mainly whitish and soft in appearance, with areas of yellow coloration and some hæmorrhages. Sections showed the growth to be almost entirely a sarcoma of mixed-cell type. Remnants of the fibroid were visible both at the periphery and amongst the sarcomatous cells. Sections from the uterine muscle at the base of the tumour failed to show any sarcoma, as did sections of the endometrium close up to the point where the tumour had ruptured.

Whitridge Williams's article of 1894, said Dr. Gemmell, still remained among the best of those on the histogenesis of sarcoma of the uterus. Judged by his standards the present growth was not likely to have arisen in the endometrium, as that membrane was normal right up to the place where the necrotic portion of the tumour had ruptured, and because the muscular uterine wall maintained its normal thickness. It might have arisen from the uterine wall, but the myoma-like tissue amidst the sarcoma cells and at the periphery of the tumour were against this view. That the tumour was apparently circumscribed did not exclude the uterine wall as a possible origin. On the other hand, this myoma-like tissue might be merely remnants of the connective tissue of the uterine wall. The history of excessive menstrual loss for 12 years was, however, suggestive of a pre-existing non-malignant condition.

Mr. W. GOUGH (Leeds) described a case of

Carcinoma of the Body of the Uterus after Interposition Operation for Genital Prolapse.

The patient, aged 70, complained chiefly of urinary symptoms—dysuria and pain, and also hæmorrhage in the urine for the previous month. There was also complaint of bearing-down pain, pain in the lower abdomen and back. Amputation of the cervix, colporrhaphy, and vesico-vaginal interposition had been done 15 years previously. Since that time she had been under the care of another surgeon, suffering from obscure urinary symptoms. On examination there was marked atrophy of the vagina, and no cervix could be felt. There was a hard mass lying posterior to the urethra and extending to the base of the bladder.

Mr. Gough said it was only the fact that he knew that the surgeon who had operated on her for the genital prolapse was in the habit of performing the interposition operation that made him suspect this mass to be the body of the uterus. Under an anæsthetic he found the anterior vaginal wall invaded by growth, which had ulcerated through about half an inch above the urethral meatus. The bladder was enlarged and extended well above the pubes. The urethra was unaffected. Microscopical examination showed the growth to be a papillary adeno-carcinoma, on the whole of the corporeal type.

Dr. F. H. LACEY (Manchester) described a case of

Combined Concealed Accidental and Unavoidable Hæmorrhage.

A 4-para, aged 33, was seen when 37 weeks pregnant, with a history of slight vaginal hæmorrhage. Although the hæmorrhage had been slight, yet her general condition resembled more that following a severe hæmorrhage. She was pale and faint, the pulse was 120 and weak; she was somewhat restless and complained of no definite pain, but of a continual ache in her abdomen and of dizziness which had been present for about seven hours; there was marked albuminuria. The abdomen was very large, tense, and tender, particularly to the right of the fundus; fœtal parts were felt indefinitely, but fœtal heart sounds could not be heard. The os admitted one finger and the placenta was felt to be covering it, but Dr. Lacey was confident that she had a concealed accidental hæmorrhage and decided to perform Cæsarean section. On opening the abdomen the uterus was found to be very distended, but there was no evidence of hæmorrhage into the wall; on opening the uterus a large quantity of amniotic fluid escaped and the cavity was seen to be occupied by twins, one placenta being in the lower uterine segment, and the other on the posterior wall of the uterus, under which, and close to the edge, was about a quart of clots. The uterus was removed. The twins weighed 6 lb. and 5½ lb.; the former, which was attached to the placenta prævia, lived 40 minutes, whereas the other child was stillborn. The mother made an uneventful recovery.

On account of the concealed hæmorrhage, said Dr. Lacey, the blood was examined and the W.R. was found to be strongly positive. This patient, therefore, had marked albuminuria, hydramnios, twins, concealed accidental hæmorrhage, placenta prævia, and syphilis.

Prof. MILES PHILLIPS (Sheffield) read a note on

Intermittent Periodic Pain as a Symptom of Carcinoma Corporis Uteri.

Attention was first drawn to this symptom, he said, in 1863 by Prof. James Simpson, the discoverer of chloroform, at a meeting of the Edinburgh Obstetrical Society. After demonstrating a specimen of carcinoma of the body of the uterus, he referred to the daily recurrence—usually at a regular hour—of intense paroxysms of pain, at first perhaps slight and intermittent, but soon reaching a high pitch of intensity, at which it continued for an hour or two, and then gradually subsided. Prof. Phillips had seen similar intermittent pains with calcified submucous fibroid and somewhat similar paroxysms of pain with retention of fluid in the cavity of the uterus from occlusion of the os. Except in these rare cases, however, this kind of pain was only to be met with, so far as he knew, in carcinoma of the body and fundus of the uterus. Eden and Lockyer (1928), in describing the symptoms of corporeal cancer, did not refer to pain of any description, which struck him as very remarkable, for in his series of 82 cases pain was definitely present in 60 (73 per cent.). A recent case in which the symptom was well marked had led Prof. Phillips to hunt through his own records of corporeal cancer. Five instances of Simpson's pain could be found in the series of 82 cases. A study of these led him to agree with Pozzi that the symptom was probably neuralgic.

The PRESIDENT was surprised to note Prof. Phillips's high percentage of pain. He himself had gone over his private cases, 34 in all, and found that in 24 there was no complaint of pain. Two of these showed dilatation of the cervix with palpable growth of the external os, but without invasion of the cervix by malignancy. It seemed unlikely, therefore, that pain was associated with attempts at extrusion. Five of his patients complained of gnawing or cramp-like pain without periodicity; four of these were operable. Five complained of pain apparently arising outside the uterus—e.g., intestinal colic from adherent intestine, suppurative appendage disease, or prolapse.

Prof. W. FLETCHER SHAW (Manchester) described a Full-term Ectopic Pregnancy, and Mr. ST. GEORGE WILSON reported a case of the same kind treated by Cæsarean section with delivery of a child, with numerous deformities, which lived 5½ months.

Reviews and Notices of Books.

MALIGNANT DISEASE.

The Surgical Treatment of Malignant Disease. By Sir HOLBURT J. WARING, M.S., M.B., B.Sc. Lond., F.R.C.S., Surgeon and Lecturer on Surgery, St. Bartholomew's Hospital; late Vice-Chancellor, University of London. London: Humphrey Milford, Oxford University Press. 1928. Pp. 667. 50*s*.

IN 1921 Sir Holburt Waring delivered the Bradshaw Lecture before the Royal College of Surgeons of England, taking for his subject the surgical treatment of malignant disease, and it is not surprising that, faced with the necessity of summarising within the limits of a single discourse so huge a subject, he should have felt prompted later to enlarge upon the theme, and finally to make it the subject of a text-book. In the original preparation of the lecture much material in connexion with the surgery of malignant disease was amassed from the records of St. Bartholomew's Hospital, while the lecturer stated definitely that he would confine himself to personal observations made during the past 25 years; but now consultation of general surgical literature has enabled him to range with full detail over the whole field, while in every chapter of this large volume personal experience plays a part, whether in advice as to diagnosis or in instruction as to treatment.

The result is a book of outstanding merit which must have entailed much sustained work. The arrangement of the matter is regional, which clearly has its disadvantages, for some repetition must be employed under different local considerations, when general precepts might have been laid down. But in consecutive chapters we have clear accounts of malignant disease as it occurs in various parts of the body, the order of these being to a great extent arbitrary. The first eight chapters, comprising nearly a quarter of the book, deal with the malignant affections of the gastro-intestinal tract from the tongue to the rectum, pride of place being due alike to the variety of growths to be anticipated and to the large field for operative procedure which has to receive discussion, although the affections of the liver, gall-bladder, spleen, and pancreas are separately treated. The next nine chapters deal with malignant disease as it manifests itself in the genito-urinary tract, including an elaborate study of malignant disease of the breast, but excluding consideration of the bladder, ovary, uterus, and vagina, to each of which special chapters are devoted. Malignant disease of the brain, intracranial tumours, and the affections of the spinal cord form a group of interesting essays, and other chapters deal with the conditions found in the face and skin, the thorax, the different limbs, and the special organs.

In each section the same orderly manner of dealing with the subject is observed. The symptoms and clinical appearances are described, so that the reader is reminded alike of the probable site of any particular manifestation and the probable interpretation of any history given by the patient; as well as warned in what direction to look for the evidence required before a diagnosis is made upon which treatment and a fair expectation of the results can be founded. When the surgeon has definitely decided, with such reaching in his mind, that an operation is necessary, the reasons for the advocacy of one or another procedure are given, as well as careful descriptions of the operative technique. The details of the various operations follow in the main the text of the author's well-known "Manual of Operative Surgery"; the instruction is sound and clear. Comprehension of the conditions which the surgeon may have before him, and of the methods which he may be advised to adopt, is assisted by profuse illustration of various malignant conditions, as exhibited in the museums, as superficially seen in the subject, as made apparent by preliminary exposure and when undergoing actual operation, while frequent diagrams are introduced justifying the advice given at various stages in the conduct of the case. Many semi-diagrammatic illustrations of the lymphatic system connected either with a particular organ or with an anatomical area are of real service in explaining the problems of glandular involvement. Notes follow on the results to be expected from surgical interference, and here a remark made by the author in his preface is significant. For while crediting the clinical records of St. Bartholomew's Hospital with being admirably kept, he points out that he has not been able to give complete statistical tables of the ultimate results of the surgical treatment of various patients, owing in great measure to the fact that during the twenty-year period, 1900 to 1919, which covers the records of the selected patients, no regular "follow-up service" was in existence. This condition of things, he says, is now remedied at St. Bartholomew's Hospital, but it is known to remain in many other large institutions, and these should hasten to imitate a valuable movement. To all the more important chapters a section is added dealing with treatment by radiological methods, and this is a place where the reader loses, by the regional arrangement adopted, the laying down with authority of some of the general principles which by this time have emerged. But Sir Holburt Waring, when he disclaims personal knowledge of the advances that have been observed under radium and irradiation treatment, is careful to provide the views of other authorities over many large fields of work.

We have here a valuable work of reference. The reader will find in its pages the material for diagnosis, treatment, and prognosis in all forms of malignant growths, the teaching being based upon wide reading and prolonged personal experience, and simplified by numerous illustrations, many of them in colour, and mostly very good. The number of cases cited is prodigious, and the author has been scrupulous to assign to others credit where credit is due. To each chapter there is a copious list of references, and a bibliography to the accuracy of which Sir Holburt Waring issues a challenge, when he states that his experience of bibliographies, as generally furnished in medical literature, has been unfortunate; the care that, no doubt, he has taken in the matter has not made the references in his book impeccable.

CHEMICAL ENCYCLOPÆDIA.

An Epitomised Digest of Chemistry and its Industrial Applications. Fourth edition. By C. T. KINGZETT, F.I.C., F.C.S. London: Baillière, Tindall and Cox. 1928. Pp. 807. 35*s*.

THE fourth edition of this useful digest has been greatly enlarged and revised. It has been the aim of Mr. Kingzett, who was one of the original founders of the Institute of Chemistry, to compile a work of reference which should be of use not only to professional chemists and chemical engineers, but to editors in search of concise information, to professional men who needed to look up something outside their own particular department of knowledge, and to the general community. The encyclopædia, as it is now called, is not intended to compete with such a comprehensive work as Thorpe's Dictionary of Applied Chemistry, but the author claims for it the position of being the only work of its kind in existence which gives so extensive a range of condensed information concerning chemistry and industry. In considering its merits, this intention should be borne in mind, for naturally the laboratory worker will not find within its compass all the information which he requires, although if journalists and publicists were to have a book like this on their shelves and make a friend and confidant of it, fewer mistakes would occur on the occasions when chemical and physical matters are referred to. The verbal accuracy of the dictionary is commendable, and in its development from a dictionary to an encyclopædia it has become increasingly interesting. The purchaser will get good value for his money.

PHYSICAL CHEMISTRY.

The Phase Rule and its Applications. Sixth edition. Revised and largely rewritten by ALEXANDER FINDLAY, M.A., D.Sc., F.I.C., Professor of Chemistry, University of Aberdeen. London: Longmans, Green and Co., Ltd. 1927. With 165 figures. Pp. 326. 10*s.* 6*d.*

A GOOD deal of rearrangement and rewriting has been necessary in order to do justice to recent advances without unduly increasing the size of this book. Of the 17 chapters included in the new edition two are devoted to systems of one component, seven to those of two components, and four and one to those of three and four components respectively, while a new chapter has been introduced on the practical application of equilibrium diagrams; this latter will be found of great value providing, as it does, a guide to the practical operations of the winning of salts by crystallisation from solution, and thus furnishing evidence of the utility of the phase rule first enunciated by Gibbs in 1877. During the 23 years of its existence this book has helped to elucidate to an ever-increasing number of students the intricacies of the phase rule, and has contributed much to the clearer understanding and more intensive study of this important branch of physical chemistry.

THE PHILOSOPHY OF MEDICAL PRACTICE.

Behind the Brass Plate. By ALFRED T. SCHOFIELD, M.D., M.R.C.S. London: Sampson Low, Marston and Co., Ltd. 1928. Pp. 326. 15*s.*

EVERY doctor who has enjoyed a long and active professional life must have amassed enough amusing and interesting experiences to make at least one volume of reminiscences. Dr. Schofield is no exception; indeed, the fact that he has been much absorbed in sociological matters has widened his circle of acquaintances. He has friends in all classes of society, and has had more varied experiences than most men. His book is not meant to be read from cover to cover, but can be opened anywhere. It is full of good stories and a genial philosophy.

PATHOLOGY.

A Text-book of Pathology. Fourteenth edition. By FRANCES DELAFIELD, M.D., and T. MITCHELL PRUDDEN, M.D. Revised by FRANCIS CARTER WOOD, M.D., Director of the Pathological Department, St. Luke's Hospital, New York, and of the Institute of Cancer Research, Columbia University. Edinburgh: E. and S. Livingstone. 1928. Pp. 1339. 55*s.*

THE fourteenth edition of this popular text-book has been carefully revised and new matter has been inserted, especially in those chapters dealing with the diseases of the nervous system, infectious diseases, and the diseases of bones and joints. Vitamins and hormones are noticed, and changes have been made in the chapters dealing with the thyroid, pancreas, lungs, and the blood. There are several new illustrations. To make room for these additions the chapter on lesions following various types of poisoning have been eliminated, for they are adequately dealt with in text-books of legal medicine, and a chapter on technique has been dropped from Part III. These changes have enhanced the value of the book without altering its character, and we have no doubt that its well-deserved popularity will be maintained.

Post-mortem Appearances. Second edition. By JOAN M. ROSS, M.D., B.S. Lond., M.R.C.S., L.R.C.P., Senior Assistant Pathologist to Royal Free Hospital; Lecturer in Pathology, London School of Medicine for Women; late Assistant Pathologist, St. Mary's Hospital. London: Humphrey Milford, Oxford University Press. 1928. Pp. 225. 7*s.* 6*d.*

IN preparing the second edition of this popular manual the author has wisely resisted any temptation there may have been to enlarge it. The text has been revised, and notes have been added on eclampsia, mediastinal tumours, subacute bacterial endocarditis, and thrombosis. Due attention has been paid to such criticisms as were called forth by the first edition, and we have no doubt that the book will maintain its popularity.

PSYCHE MINIATURES.

Medicine and the Man. By MILLAIS CULPIN, M.D. Lond., F.R.C.S. Eng. London: Kegan Paul, Trench, Trübner and Co., Ltd. 1927. Pp. 67. 2*s.* 6*d.*

The Constitutional Factor in Disease. By ARTHUR F. HURST, M.D. Oxf., F.R.C.P. Lond. Pp. 93. Same publisher and price.

THESE two additions to the medical series of Psyche Miniatures form, like the previous volumes, well-written approaches to the study of large and deeply interesting subjects. Dr. Millais Culpin discusses medicine and man, as the subject of medicine, from the neurologist's point of view, opposing the axiom that where an organic disease cannot be found a functional nervous disease must be thought of. He protests against the assumption that changes in mechanism always precede and cause mental processes—lightly to make this view a basis of clinical medicine involves, as he points out, facing the greatest problem that the philosopher can be asked to solve. He would restrict the word neurosis, which is now applied in a haphazard fashion to mental and physical conditions, to disturbances that can be described in terms of physiology—actions in which the neuron plays part, and the word psychosis he would have employed where the psyche is in question. Inquiring into the background of a neurosis, he points out that the doctor is presented with a heterogeneous group of disorders marked by an absence of post-mortem findings—for instance, dysmenorrhœa, asthma, many dyspepsias, miners' nystagmus, and D.A.H.—where a proper attempt to investigate the emotional side of the patient is very usually absent. The public he finds insufficiently concerned in the matter, preferring to ignore the existence of sufferings which do not prevent the victims from carrying on their work under unsuspected difficulties. Medical students remain uninterested in things which will play no later part in examinations, and quacks of all sorts thus obtain their opportunity. Dr. Culpin's remedy, put briefly, is that the various phobias, inhibitions, and obsessions now regarded as text-book curiosities, and too often unrecognised as they recur in medical practice, should be studied as phenomena of importance in establishing diagnoses, and suggesting both outlook and treatment.

Dr. Hurst's essay is founded on an address delivered before the Ulster Medical Society, to which additions have been made in the light of recent investigations, sometimes carried out at his clinic in the New Forest, and sometimes by other observers to whom due reference is made. He recalls to our mind the famous studies of T. Laycock and Jonathan Hutchinson now neglected, and urges that a study of the constitutional factor in the acquisition of disease would be a promising field for research. But the chapters which follow do not discuss either the fundamental meaning of constitution nor the difficult problems of heredity, for these could not be treated in any general way in so confined a space; he considers here only the constitutional factor in certain pathological conditions in which he has been specially interested for many years. No allusion is made to the inherited liability to such infections as tuberculosis, to certain anatomical abnormalities that are inherited, to the "inborn errors of metabolism" described by Garrod, or to the familial blood disorders, but Dr. Hurst discusses the gastric diatheses, achylia gastrica, Addison's anæmia, diabetes, nephritis, hyper- and hypo-piesia, and asthma in an informing manner, with practical suggestions for treatment.

THE LANCET.

LONDON: SATURDAY, MARCH 24, 1928.

PULMONARY FIBROSIS.

FEW diseases have suffered more vicissitudes of nomenclature than this pathological condition, and although it is convenient to refer to is as an entity, it is perhaps not altogether accurate to do so. BAYLE named it melanosis, SUTTON fibroid degeneration, CORRIGAN cirrhosis, ADDISON grey induration, WILSON FOX chronic pneumonia, and certain continental writers interstitial pneumonia. Few diseases, also, have produced such confusion of ideas as to their causation. RAMAZZINI,[1] whose alert mind marked many curious facts, described in his "Diseases of Tradesmen" a form of the disease in stone-cutters due to a "subtile Dust" and in "dissecting the Corps of such Artificers" he found the lung "stuffed with little stones"—obviously the pneumonoconiosis of our modern nomenclature. Later, BAYLE, LAËNNEC and others of the early nineteenth century French school of pathologist-clinicians described another variety, the fibroid disease of pulmonary phthisis, and though their descriptions are not always conclusive, it is evident they were dealing with cases of chronic pulmonary tuberculosis. Then, after more than half a century of confusion, came the classical monograph of CLARK, HADLEY, and CHAPLIN,[2] which separated off from the two conditions mentioned above the non-tuberculous pulmonary fibrosis of childhood resulting from the broncho-pneumonias of measles and pertussis. The account of the disease given by these writers still remains the standard work from which writers of text-books draw their descriptions. Unfortunately the coloured plates are not reproduced. This is a pity, for they are wonderfully good illustrations of the morbid anatomy of the various types of the disease. The picture of Addison's grey induration, especially, is a beautiful work of art showing the pigmented mottled lung and the thin white intersecting bands marking off the areas and planes.

Not a great deal has been added to our knowledge of pulmonary fibrosis in childhood since the publication of the last-named monograph. As in the case of other diseases in which the onset is insidious and the course extremely chronic, few observers are fortunate enough to watch more than one or two cases through to the end, and post-mortem inspections, as HODGKIN called them, are hard to come by. Moreover, by the time the autopsies occur the picture has generally been completely spoiled by terminal infections. And so precise knowledge on many points is still woefully lacking, and teaching on the disease almost non-existent. Nowadays, when the various State schemes of the tuberculosis and school medical services require, for statistical purposes, a label if not a diagnosis for these cases, it is small wonder that the fibroid disease of childhood often defies the ingenuity of the pigeon-hole manufacturer. If the cases are not notified as tuberculosis—and the bulk of them are certainly non-tuberculous—they run the risk of being overlooked under the various schemes of treatment provided, whilst to notify them is generally to falsify statistics. Amongst the recent attempts to throw new light on pulmonary fibrosis may be mentioned Dr. LEYS'S monograph.[3] The author has framed his title to cover as far as possible all the clinical forms of the disease. A large part of the book is an able restatement of CLARK, HADLEY, and CHAPLIN'S work, with recent descriptions and cases added to bring the subject up to date. Dr. LEYS does not contribute much that is new—perhaps it is hardly fair to expect it on such a subject—but when he opens his chapter on the origin of fibrosis with the words "fundamental phenomena in reaction to injury are those of healing; without them, there is no disease but death" we feel he has added to the confusion. Dr. LEYS considers that the lung in disease has become something of a Cinderella in medicine. The morbid anatomy of fibrosis certainly merits that description, but we are not so sure that the analogy applies to the rest of the picture. It is not so much neglect as the inherent difficulties of the subject which have made progress slow. The radiological contribution, for instance, is nowadays by no means despised and neglected, as Dr. LEYS himself demonstrates. On the bacteriological side he devotes a large amount of space to Pfeiffer's bacillus, which, he suggests, may be the causative organism in many cases. Sufficient data are given to make this view attractive, but the pursuit of this ubiquitous organism generally leads the worker, at his long last, into the mists of uncertainty. The difficulty is often not to find Pfeiffer's bacillus but to avoid finding it, and we see no reason why much that is claimed for this bacillus might not be credited to some of the other organisms which frequently infect the respiratory tract. Dr. LEYS has made out a good case for further investigation, however, and we hope he will be able to follow it up.

Another recent piece of research is that of Dr. W. BURTON WOOD published in our current number. Dr. WOOD has traced and examined a series of cases which had been diagnosed as fibroid lung during childhood. He has grouped them into four classes by the aid of the clinical notes and then regrouped them at the time of the follow-up examination 13 or more years later when the cases have reached adult age. By this means he has gone a considerable way towards answering some of the puzzling questions of this disease—e.g., what becomes of these children with fibroid lung? Do they grow up or drop out in the struggle? And how many become bronchiectatic? Broadly speaking, the answer given is that even with extensive fibrosis a bad prognosis is by no means inevitable and bronchiectasis by no means the rule. Dr. C. D. S. AGASSIZ and Dr. W. J. GILL[4] have written a careful account of the clinical condition from cases in children which have come under their care at High Wood Hospital. Several important doubts are settled by these writers. They found, for instance, that only 8 per cent. of their cases gave a positive Wassermann reaction, whilst antisyphilitic treatment of these cases failed to yield

good results. The writers are at pains, also, to differentiate clearly between chronic pulmonary fibrosis and tuberculosis in childhood. We wish those who are prone to see pulmonary tuberculosis in every ailing child might read and mark their account But the most original contribution made is the work they have done on the cyanosis so commonly associated with fibroid lung. The blood-oxygen of these cases was found to be diminished owing, it is suggested, to the failure of aeration in the part of the lung affected —the "unaerated shunt" of LUNDSGAARD and VAN SLYKE. Pulmonary tuberculosis in childhood, on the other hand, does not show this diminution of blood-oxygen, presumably because the disease is less likely to be attended with extensive production of fibrous tissue. It would seem, therefore, that the component parts of the problem of pulmonary fibrosis are slowly yielding to careful research.

THE N.H.I. AMENDING BILL.

WE summarised last week the main provisions of the National Health Insurance Bill now before the House of Commons. The new Bill makes generous concessions to insured persons and will result in a considerable measure of simplification in the administration of the Act. Under the arrears scheme, which is suggested, the genuinely unemployed person will not be penalised as he is under the existing Acts. At present he ceases, after a period of 12 months' unemployment, to be insured at all; sickness and disablement benefits drop out, although he remains entitled to medical benefit. Under the new scheme the insured person when out of work will have a rubber stamp impressed at the appropriate place on his card by the local employment exchange, and such stamp will count as a contribution stamp. Domestic servants and agricultural labourers, who do not come under the Unemployment Insurance Act, will benefit under the arrears scheme. All insured persons will get cash benefits during the last nine months of insurance, that is, so long as they are entitled to medical benefit. The Bill makes no change in the rates of contribution payable by employers or employed, and the liability of the Exchequer towards the cost of the scheme remains at one-seventh of the cost of benefits and administration in the case of men, and one-fifth in the case of women. The approved societies in many areas are badly hit by the heavy sickness benefit claims, which in themselves mean loss of contributory income, and to excuse arrears would make many of these societies insolvent; their funds are to be recouped therefore by a Government grant. With unemployment at its present level, the cost to societies of forgoing collection of the penalties in respect of arrears due to genuine unemployment is estimated at £680,000 a year. It is proposed that, while the present rate of unemployment continues, an annual grant of £500,000 towards this cost shall be distributed to approved societies out of existing and prospective surpluses in the stamp sales account. The societies will welcome the simplification in administration which the Bill provides. At the present time an enormous number of arrears notices have to be sent out, something like 2,500,000 per annum; these will be reduced to 500,000. It is estimated that the scheme will relieve the societies of three-quarters of their arrears difficulties.

So much towards smooth working of administrative machinery. The Bill, if it goes through, will provide a new additional benefit, under the control of the approved societies, but dependent on their having an available surplus. Provided the money is available an approved society will be able to secure special treatment, for those of its members who require it, at any "charitable" institution where this treatment is given, by making contributions to the funds of such an institution. The first schedule contains a list of additional benefits from among which the approved societies may make a selection of the benefits to be provided for their members out of a disposable surplus—including the additional benefits specified in the existing Acts, others which have been added by Regulations and the new benefit granted in Clause 4 of the Bill. These were set out last week in tabular form, and it will be seen that there is no material increase in their scope, they still form no part of the statutory medical benefit, and they are outside the purview of insurance committees. The distribution of additional benefits is thus left entirely to the discretion of the societies which are in the happy possession of disposable surpluses. Some even of the wealthiest societies have found the cost of dental benefit and optical benefit beyond their means and have been compelled to limit the scope of these schemes. The approved societies are very jealous of their freedom to select and to define precisely what additional benefits shall be given and the extent to which they shall be granted. This is part of the autonomy granted to them by the original Act. But so long as the open competition for insured members remains, and so long as the societies have undisputed control over their surpluses the anomaly of inequality of benefit must continue.

The amending Bill is, as we have said, of interest to the medical profession for its omissions rather than for what it contains. To complete the scheme of medical benefit and to make it available for every insured person would require drastic changes in policy and appropriate legislation. It is natural to inquire what is the significance of the striking omissions in the Bill. Insurance committees which were supposed to be doomed are after all to be retained; they now have charge of medical benefit, and when the additional benefits become statutory these will be administered presumably by the same committees. Most remarkable is the omission of any scheme for pooling surpluses of approved societies, even to a partial extent. Pooling of surpluses would lead to central administration of additional benefits under a scheme whereby they would be available for all insured persons; but this desirable object is out of reach until the Treasury is prepared to make substantial grants for the purpose. The only suggestion that the Government policy is looking in the direction of extending medical benefit to include additional benefits is contained in the memorandum explanatory of the Bill to the effect that, if and when any of these forms of treatment are made generally available to all insured persons as statutory benefits, their administration would be transferred to the insurance committees For the present we must perforce remain content with medical benefit in its general practitioner form. The much-needed help in diagnosing disease by means of laboratory facilities with the services of pathologists and specialists is not forthcoming, and there appears to be little prospect of these services materialising while we labour under the present financial stress. Unless, that is, a new sense of relative values should awaken among our rulers.

IMMUNISATION OF HOSPITAL STAFFS.

WE can to-day successfully protect human beings by immunisation against cholera, diphtheria, scarlet fever, small-pox, and the typhoid group of infections. We can also produce active immunity against measles by giving human convalescent serum five to eight days after contact with a patient in the infective stage—a modified attack results and active immunity is attained. Against how many of these diseases should a responsible authority advise the general public or nursing staffs to be immunised? It is possible to over-insure against risks which are small and a too-zealous advocacy of multitudinous immunisation against diseases of rare occurrence will surely alienate the moderate man. As regards the staffs of fever hospitals a decision is not difficult; the time has arrived when a conscientious medical superintendent must feel more than a little perturbed at any persistence of diphtheria and scarlet fever amongst his nursing and ward staff, and at the unwisdom of allowing any nurse positive to the Schick or Dick tests to remain on duty. But what of the staff of general hospitals? In America the matter is being taken very seriously, and Surgeon J. P. LEAKE [1] of the Federal Public Health Service, has recently suggested a programme for superintendents who wish their nurses to take no risks. It is a formidable one and involves 15 visits to the physician between "day zero" and the fifty-third day, two more visits seven months later, with 20 injections in all, the nurses finally being immune to small-pox and the typhoid fevers and having been converted from "Schick- and Dick-positive" to negative. We suspect that the comment of the matron of any of our large metropolitan hospitals would be brief and pointed. Nevertheless there is no escape from the logic of the position; each of the diseases in question does attack a number of nurses, and when diphtheria or scarlet fever is prevalent and nurses are liable to be told off to care for patients who come out with these diseases in the wards, it is a clear duty to immunise them, unless they are found to be naturally immune. It is another question whether the incidence of these two diseases amongst the general body of hospital nurses would justify insistence on immunisation in the case of nurses who may be reluctant to have it; most authorities would feel their duty had been discharged in making immunisation available to those nurses who desire it. Similar reflections apply to the general public; in institutions or communities where these two diseases are constantly present, responsible authorities do not hesitate to urge immunisation against them. Where certain diseases are absent in normal times—e.g., typhoid fever in England—the average person will consider immunisation unnecessary.

Much will necessarily depend on what may be called the technique of immunisation, and especially on reduction in the number of injections so far as this can be achieved without sacrificing efficiency. Investigations now in progress group themselves along four lines: simultaneous injections against several diseases, increasing the immunising power of each injection while avoiding the production of reactions, combining the test and the immunisation in one injection and, finally, obtaining higher efficiency by spacing the injections with progressive increase in dosage. Along all these lines much progress has been made, and we may look forward to a time in the near future when successful and simultaneous immunisation against these various diseases will be readily attained by a smaller number of injections and tests than that suggested in Dr. LEAKE's article. A. CASTELLANI [2] immunised simultaneously against three paratyphoid fevers and cholera, producing agglutinins to all of them. M. WEINBERG and A. T. GLENNY have produced antitoxin to two, three, or four gas gangrene organisms in the same horse. J. P. KINLOCH [3] and others have immunised children jointly against diphtheria and scarlet fever, and P. DESCOMBEY and G. RAMON [4] have immunised against typhoid and tetanus, giving at the same time salvarsan or other drugs called for. But it seems fairly clear that a great excess of one antigen will lessen or suppress the immunity response to a second antigen given simultaneously, and that the capacity of the animal body to react is a more or less limited quantity which can be wholly apportioned to one antigen or divided amongst several without sacrifice of efficiency if the quantities are properly balanced. The immunologist can readily increase the immunising power of diphtheria and scarlet fever prophylactic, but he must never lose sight of the possibility of reactions, non-specific as occur commonly enough in diphtheria prophylaxis, or specific as the "miniature non-infectious scarlet fever," which can be produced by too rash a dosage of scarlet fever toxin. Gradually the present prophylactic toxins and toxoids are being increased in efficiency. A. SORDELLI and R. SERPA [5] showed that toxin-antitoxin floccules are antigenic, and H. SCHMIDT [6] has begun to use this antigen on a large scale, recommending one injection only; GLENNY [7] has further shown that toxoid-antitoxin floccules are also highly antigenic and produce satisfactory immunity in animals with one injection. We understand that these floccules are being tried in England at present in a course of two doses, the aim being later to try one dose only. Attempts to combine the Schick test toxin and diphtheria immunising antigen in one dose were made some years ago in a somewhat indefinite way in the original Behring toxin-antitoxin mixtures; W. H. PARK uses his first toxin-antitoxin injection subcutaneously to indicate whether the patient is Schick-positive or not, and simultaneously to immunise. In young children this is so successful that he has employed the method in 100,000 young children; in older children, and in adults, the Schick response is liable to be blurred. This method is not possible with the toxoid-antitoxin mixture used in England, for this contains presumably no free toxin. A combined indicating and immunising mixture, D.P.I.M., to be given intradermally, has been described by GLENNY,[8] and is still under investigation. It is highly probable that the present routine weekly doses of diphtheria and scarlet fever prophylactics, though administratively convenient, are not spaced for optimal immunisation. GLENNY has shown that horses being immunised against tetanus give a much better yield if allowed to rest a month after the first injection before the course is continued, and RAMON [9] has advocated a rest of several weeks for human beings after the first diphtheria prophylactic dose.

In view of all this work we may look forward with some confidence to a day in the near future when a nurse reacting positively to the Schick and Dick tests, and wishing to be immunised against diphtheria and scarlet fever, will need no more than three injections, increasing in dosage at monthly intervals, and thereafter a Schick and Dick test. If antityphoid immunisation be also advisable, the typhoid antigen might be given simultaneously in the three monthly doses. We may also hope that some day the immunising injections will also be indicating mixtures and will render manifest the stage of immunity reached.

LEICESTER ROYAL INFIRMARY.—The Leicester and County Saturday Hospital Society, having accumulated a reserve amounting to £30,000, has granted £10,000 of it to the Leicestershire Infirmary. Last year the society raised £44,000; in a quarter of a century it has collected £540,000. The rebuildings and enlargements of the infirmary, which are now in hand, will cost £90,000. It is officially stated that in one week recently it dealt with 1750 accident cases.

Annotations.

"Ne quid nimis."

PREVENTION OF BLINDNESS FROM OPHTHALMIA NEONATORUM.

IN 1920 Dr. Addison as Minister of Health appointed a departmental committee to investigate the causes of blindness. Two years later in its final report [1] this committee made certain recommendations about the prevention of ophthalmia neonatorum, and the Council of British Ophthalmologists has now issued a statement [2] founded on replies to a questionary, addressed to all the important ophthalmic centres in Great Britain, in order to find how far these recommendations have been put into practice. The first of them was as follows: "That in every area, whether urban or rural, the Ministry of Health should take measures to secure the provision of suitable hospital accommodation for babies suffering from ophthalmia neonatorum and for their mothers." In this subject the answers were satisfactory except for 10 out of 51 districts in England and 1 out of 11 in Scotland. The second recommendation was that the Ministry should take steps to ensure that adequate nursing provision is always available for cases of ophthalmia neonatorum which are not admitted to hospital. The replies to the question on this matter were nearly all favourable, but the Council considers that they are too optimistic; whereas cases coming to the ophthalmia neonatorum centres from the immediate neighbourhood nearly always do well, those coming from outlying areas are—owing to difficulty and delay in transport—seen at a time when irreparable damage has often already been done. The third recommendation refers to facilities for consultation with an ophthalmic surgeon and for bacteriological investigation. In these respects the Council finds that the conditions are sufficiently satisfactory. The fourth recommendation advocates arrangement for pupil midwives to visit ophthalmic hospitals, or the ophthalmic departments of general hospitals in order to get direct experience of ophthalmia neonatorum. Here the condition of affairs appears still to be most unsatisfactory. There are facilities in only 24 out of 51 districts, and in 9 out of the 24 districts where instruction is given it is only by lectures and not practical. In London, at St. Margaret's Hospital, and to some extent at Moorfields, ample opportunities exist, but even there advantage is not being taken of the ample and full organisation for teaching.

In reply to further questions as to the number of cases of defective vision and blindness resulting from ophthalmia neonatorum, the Council is able to report excellent results in some of the large towns. In London, out of 2869 patients treated at St. Margaret's Hospital one was blinded in both eyes, four in one eye, 30 had both eyes impaired, and 56 one eye impaired. The report finishes with the following important recommendations:

That the Ministry of Health be advised:—

(1) That the whole country be mapped out into districts, each of which should have an ophthalmia neonatorum centre; and that all large towns that have an ophthalmia neonatorum centre should undertake the treatment of cases occurring not only in the towns but in the surrounding areas.

(2) That, where necessary, existing centres should be made responsible for larger areas than at present, and that arrangements be made for ambulance transport of both mother and baby if required.

(3) That it should be made a compulsory part of the training of district nurses to attend one of these centres for practical instruction in the application of treatment in such cases.

That the Central Midwives Board be advised:—

That, in accordance with the recommendation of the Departmental Committee, as centres for the treatment of ophthalmia neonatorum are established, it should be made a compulsory part of the training of midwives to attend one of these centres for practical instruction in the recognition of these cases.

That the General Medical Council be advised:—

That it should be made compulsory for all students to attend once at least at one of the ophthalmia neonatorum centres for practical instruction in the management and treatment of these cases, the most convenient time in the curriculum being during attendance at the course on fevers.

Something like 100 cases of ophthalmia are brought each week to the notice of the public health authority in England and Wales, but damage to the eyes from this kind of infection is as unnecessary as it is disastrous and we welcome these proposals that greater care should be taken to prevent it.

SICKNESS AND AGE.

TWELVE months ago an officer of the American Public Health Service[1] published an investigation of data covering a ten-year period relating to absences from work on account of invalidity among employees of the Edison Electric Illuminating Company of Boston, U.S.A. It established a number of interesting points, such as the influence of paying wages during sickness upon increasing absenteeism for short periods; the fact that on an average each male lost 8·9 calendar days yearly through disability, and each female 14·0; that sickness caused 12 times as many absences as accidents among men, and 171 as many among women; and that respiratory diseases accounted approximately for one-half of all absences. A further study has now appeared,[2] dealing with the three years 1922–24, in which the general incidence of sickness is presented in the form of simple graphs. Accurate facts regarding the influence of occupation in causing sickness have proved difficult to elucidate, owing on the one hand to the way in which individuals of different physique and health naturally select different types of occupation, and on the other to the way in which a slight disability, such as minor respiratory illness for a telephone operator, may necessitate absenteeism from one occupation but not from another. The influence of age is shown to vary with the length of the sickness; thus absenteeism for sickness lasting less than four days varies for males from 872 absences per thousand on the pay roll under age 25, to 372 per thousand at ages 55 and over; for absences lasting from four to seven days age exerts little if any influence, the absences averaging close to 226 per thousand at each age, but absences lasting eight days and over vary from 130 per thousand at ages under 25 years, up to 211 from ages 55 and over. It is somewhat unexpected to find that youth experiences more minor sickness than does age, but this has also been disclosed by British investigations. Length of service was found to influence absenteeism so advantageously that those who had been five or more years with the company experienced less sickness than those of shorter service by 41 per cent. for one to three day cases, by 20 per cent. for four to seven day cases, but by only 2 per cent. for cases lasting eight days and over. Thus is seen how getting settled into an environment minimises the risk of succumbing to sickness. Here again, as in other inquiries, especially regarding the incidence of industrial accidents, is displayed the advantage of a permanent personnel and the disadvantages of a high labour turnover. A tendency for those who experience much sickness to experience an undue number of industrial accidents has also been brought out in other inquiries; a further point has now emerged—namely, that a definite correlation exists between industrial and non-industrial accidents; that is to say, the man who is more than usually likely to sustain an accident during work is also more

[2] Sickness Among Persons in Different Occupations of a Public Utility, ibid., vol. xliii., No. 6, February, 1928.

than usually likely to sustain an accident outside working hours. Clearly the cause which suggests itself as common to both periods is the personal factor, upon which attention is to-day being so much concentrated.

THE INNERVATION OF MALIGNANT NEW GROWTHS.

THERE is at present among pathologists a fairly general agreement that malignant new growths are not innervated. This view is based, partly at any rate, on the negative results obtained by a number of investigators when applying to neoplasms the methods usually employed for the demonstration of nerves in normal tissues. But it is also implied in our present conception of neoplasms as autonomous independent masses of cells which have passed out of the control of the organism in which they grow. A few years ago Itchikawa [1] and his collaborators claimed to have demonstrated nerves in tumours. But another Japanese investigator, Nakamoto,[2] was unable to confirm Itchikawa's findings for malignant tumours, while he could demonstrate nerves in benign tumours. Prof. Horst Oertel, of Montreal, has now published a preliminary report [3] in which he claims to have demonstrated nerves in malignant neoplasms. His observations were made on human material and include both sarcomas and carcinomas. The method employed was a modified Bielschowsky method, which depends upon impregnation with silver nitrate. The paper is illustrated by a number of micro-photographs which give a good idea of the structures which Prof. Oertel identifies as nerve-fibrils. In a tissue such as a tumour, which has lost its normal structure, it is clearly much more difficult to differentiate between nerve-fibrils and delicate young connective tissue elements, and further confirmation is required before Prof. Oertel's conclusions can be accepted. A confirmation of his findings would, indeed, as the author points out, involve a profound reorientation of our present conceptions of malignancy. We would have to admit (to use his words) that "the tumour problem extends beyond the tumour cell to the whole functional and structural complexity of the tumour organisation and growth. Indeed, the conception of independence and autonomy in tumour cells, if these observations are further substantiated, will have to be modified or interpreted accordingly." There is already a certain amount of clinical evidence, which has been emphasised particularly by Sir Lenthal Cheatle,[4] that certain squamous cell carcinomas and rodent ulcers of the skin have a definite relationship to the distribution of cutaneous nerves. The problem is intimately associated with the question of the existence of trophic nerves, and Prof. Oertel's observations may serve as a stimulus for the further investigation of this difficult subject.

ALCOHOLISM AND PELLAGRA.

A CONNEXION between alcoholism and pellagra has been noticed by various observers, but lately seems to have been lost sight of. Attention is again drawn to it by a paper by J. V. Klauder and N. W. Winkelman,[5] who give an account of 100 cases of pellagra, studied at the Philadelphia General Hospital, in which a diagnosis of pellagra was established. Though no percentages were worked out, the occurrence of alcoholism among the patients seems to have been high. The condition was usually severe, and it was often found that pellagra had developed after a continuous debauch of six or eight weeks during which the patient had consumed very little besides alcohol; spaghetti is given in one instance as the only other article of diet and baked beans in another. It is recalled that observers in Italy, Spain, Cuba, and the United States have noted the connexion between alcohol and pellagra, and the conclusion is reached that alcoholism predisposes to development of the disease, which Klauder and Winkelman are apparently inclined to regard as chiefly an intoxication. Criticism of this view was fairly expressed in the discussion [6] which followed the reading of their paper before the Section of Dermatology of the American Medical Association. Dr. J. F. Schamberg put forward the alternatives, that the action of alcohol depends on the digestive disturbance caused by prolonged drinking bouts, or that the alcohol is itself responsible for the pellagroid symptoms. He referred to the work of Dr. J. Goldberger, who has produced pellagra-like symptoms in dogs and rats by purely dietetic means, as being very convincing. Dr. E. S. Lain, of Oklahoma, said that pellagra in the Southern States is very common among children and young adults, in whom alcoholic habits had not yet developed, and also in certain poor communities where the Volstead Act is taken very seriously. He suggested that the part played by alcoholism may be chiefly economic. Dr. E. D. Crutchfield emphasised the impossibility of properly nourishing an alcoholic or a lunatic and thought that the evidence about the relation of pellagra to alcohol confirms the theory that it is a deficiency disease. Dr. J. B. Shelmire pointed out that pellagra was not diagnosed in the States until 1907, though the diet after the Civil War, for instance, must have been extremely poor. Dr. Klauder finally summed up. He said that, of course, he did not regard alcohol as the universal ætiological agent in pellagra; clearly, in the Southern States, it could not be so; but he believed that in the Northern States it is a strong predisposing cause. This seems a reasonable view. In some areas, no doubt—particularly, though not exclusively, in those where much maize is eaten—pellagra has a wholly dietetic origin; but in others, where the diet is not normally deficient, some other factor is necessary to render it so for certain individuals. Thus only can the occurrence of sporadic cases, even in England, be accounted for.

VORONOFF'S GRAFTING EXPERIMENTS: AN OFFICIAL INVESTIGATION.

The Board of Agriculture for Scotland has issued an official report on the work and claims of Dr. Serge Voronoff. It will be remembered that a delegation recently visited Voronoff's experimental farm in Algeria in order to investigate his grafting experiments on animals. The delegation consisted of Dr. F. H. A. Marshall and Dr. A. Walton of Cambridge, Dr. F. A. E. Crew and Mr. W. C. Miller, F.R.C.V.S., of Edinburgh. The objects of the visit were; (1) to witness the applications of testicular grafting to animals of agricultural importance; (2) to examine certain animals already subjected to this technique; (3) to examine and report upon the claims made by Voronoff concerning the economic value of this method in the field of practical live stock breeding. As an instance of rejuvenation the delegates were shown the bull "Jacky," an account of which is published in Voronoff's "Study of Old Age and my method of Rejuvenation." This bull had attained 17 years of age, and had been useless for stud purposes for two years when grafted. It was claimed that within four months of operation there had been a complete disappearance of the usual signs of old age and a return of potency. Three years after the operation, Jacky began to show once again enfeebled reproductive powers and a second operation was performed with a similar gratifying result. Voronoff regarded this as furnishing a complete and unqualified substantiation of his claims concerning rejuvenation. The British delegates are of the opinion that whilst the case of Jacky supports Voronoff's hypothesis it cannot be accepted as a final and conclusive proof. In the case of stud bulls 10 to 15 years is not a very exceptional age at which

[1] Bull. de l'assoc. franç. pour l'étude du cancer, 1924, xiii., 569, 626. [2] Gann, 1926, xx., 10.
[3] Canad. Med. Assoc. Jour., 1928, xviii., 135–139.
[4] Brit. Med. Jour., 1903, i., 904; ii., 1515; and 1908, i., 437.
[5] Jour. Amer. Med. Assoc., Feb. 4th, p. 364.
[6] Jour. Amer. Med. Assoc., Feb. 4th, p. 371.

an animal may retain its sexual vigour, and under rare conditions it may be retained still longer. It is also conceivable that Jacky at the time of grafting was suffering from transient ill-health, and the fact that his recovery occurred in spring or early summer may not be without significance. But even if the efficiency of grafting be admitted it must be remembered that in Great Britain the supply of high-class sires in their prime is adequate, and that for this reason grafting is not likely to be of economic value. In spite of his rejuvenation, the fertility of Jacky was low since only six calves arose as the result of 18 services. A low fertility ratio in a bull is a marked disadvantage.

The second series of experiments examined by the delegates were those on rams. It has been claimed by Voronoff that not only are the quantity and quality of mutton and wool improved by grafting rams before puberty, but also that this improvement is transmitted to the next generation. The delegates were of the opinion that these experiments had been carried out without the employment of sufficient statistical safeguards. The sheep used for the purpose came from a heterogeneous type of flock and it was felt that no precaution had been taken to avoid all possibility of "unconscious" selection of favourable types. Throughout the greater part of the year, the sheep were under the sole charge of native shepherds, who, though undoubtedly responsible and competent herdsman, could scarcely be expected to appreciate the finer points of a critical experiment. The possibility that nutritional inequalities may have affected results could therefore not be excluded. The method of control was also unsatisfactory. Small isolated experimented flocks were compared with a much larger population which received the off-types from the flocks selected. The average weights of the controls would, therefore, be influenced by the weights of rejected animals. The claim of Voronoff that the improved characteristics shown by the grafted rams are transmitted to the offspring involves the acceptance of a principle of heredity which has not yet been substantiated in the realm of science. Such a claim would require to be supported by the most critical and extensive research before being accepted.

To sum up, the delegation was not satisfied that Voronoff had proved his thesis, either in the case of the rejuvenated bull or of the grafted rams. Even should subsequent experiment carried out with better safeguards against error confirm Voronoff's results, they doubt whether these results would have any economic value to the British stock breeder. Their conclusions are in harmony with those already expressed in various reviews of Voronoff's work that have appeared in our own columns. Voronoff's claims have had wide publicity in popular and agricultural papers. It is highly desirable in the view of the official delegates, "that the matter be put to further and more critical test in this country, where conditions are more favourable to scientific control."

SICKLE CELL ANÆMIA.

Dr. E. V. Hahn,[1] who reports an illustrative case, remarks that since sickle cell anæmia was first described by J. B. Herrick in 1910, about 20 papers have been published describing the clinical features of the disease and the peculiar behaviour of the red corpuscles under various conditions. Sickle cell or drepanocytic anæmia is found only in negroes with the sickle cell trait—that is, whose red cells become distorted into sickle-shaped cells under certain conditions. This trait is compatible with perfect health and a long life; it is a hereditary characteristic, behaving as a dominant according to the Mendelian law of heredity. A correlation appears to exist between the severity of the anæmia and the number of sickle cells in the circulating blood. Symptomless individuals with the trait have few or no sickle cells in their blood. The clinical picture of the anæmia closely resembles that of familial hæmolytic jaundice with the following differences. In sickle cell anæmia the resistance of the red corpuscles is increased or normal, while in familial hæmolytic jaundice it is much decreased; in the anæmia the spleen is only occasionally enlarged, whereas in familial hæmolytic jaundice splenomegaly is constant; in the anæmia there are usually certain features not present in the other condition—e.g., ulcers of the leg, joint pains, and crises of abdominal pain. Dr. Hahn describes a method of producing sickle cells in vitro from apparently normal but susceptible red corpuscles freely suspended in saline solution and for fixation of them in their characteristic shape. The factors which precipitate the distortion of cells in the living subject and cause excessive distortion are unknown, but anoxæmia is a possible factor. Early splenectomy is said to be advisable in sickle cell anæmia; in the two cases observed by Dr. Hahn much clinical improvement followed this operation, although the sickle cell trait remained unchanged.

[1] Amer. Jour. Med. Sci., February, 1928.

THE COMPLETE HOSPITAL.

Captain Stone's book on "Hospital Accounts and Financial Control" is already familiar to most people concerned in hospital administration; as head of the accountant's department of St. Thomas's Hospital he has enjoyed abundant opportunities of learning the organisation and watching the modern developments of institutions for the relief of suffering. He is, therefore, much more than a mere financial expert, and the large and elaborate book now before us[1] is a remarkably complete account of methods of hospital management. It even includes details of the equipment of some of the great American hospitals, which suggest that if the United States has something to learn from us, we are not the sole depositories of practical wisdom in this matter. But the book is not a mere collection of facts. It discusses, fairly and reasonably, the outstanding questions of hospital policies, such as the future of the voluntary system, its relation to the poor-law, the need of coördination, and so forth. Never has the intricacy of the hospital machine been so clearly brought out as in Captain Stone's book, for, indeed, the literature of this side of the subject is sparse. Writing for doctors and secretaries, matrons and nurses, and boards of management, he is terse and practical. We learn how stores ought to be bought and arranged, records of cases made and filed, accounts kept, kitchens arranged, and meals served; we even have inventories of the contents of well-equipped wards and nurses' bedrooms. Captain Stone does well to insist upon the importance of good cooking both for patients and staff. "The operation may have been very successfully performed, and the medical and nursing care beyond criticism, but if the food and its service is unsatisfactory, the sum total in the eyes of the patient is a failure." It is notorious that in many hospitals both cooking and the service of meals are unsatisfactory, partly, no doubt, because of the inherent difficulty of providing meals in large number and often in great variety, but chiefly because the importance for the sick of well-cooked food attractively served is insufficiently recognised. But what hotels can do ought not to be impossible for hospitals, and the one metropolitan hospital which has a dietetic department finds that many cases which might otherwise have to be admitted can be treated quite safely at home by its help, while cases of diabetes which have been admitted can be discharged much sooner and their treatment continued at home. Thus economy and rapidity of cure may go hand in hand.

The best methods of hospital planning and construction are still an open question, and Captain

[1] Hospital Organisation and Management, including Planning and Construction. By Captain J. E. Stone, M.C., St. Thomas's Hospital. London: Faber and Gwyer, Ltd. Pp. 642. 21s.

Stone devotes two long and valuable chapters to a subject which lies at the root of the whole matter. Varieties of method are described whether applicable to general or specialised institutions; there are chapters on fire prevention, on hospital law as affecting the institution itself and its staff, on the advantages of coöperative purchasing, on the various methods of appealing for money, and the virtual exhaustion of "whirlwind campaigns" and "spectacular publicity methods." Stress is laid upon the practical importance of creating a central bureau for the collection and classification of information of all kinds relative to the inner working and activities of hospitals. Such a bureau has long been needed, and the lack of it is more keenly felt every year. At present King Edward's Fund, the Hospital and Medical Services Department of the Joint Council of the British Red Cross Society and the Order of St. John of Jerusalem, and the Hospital Officers Association all do something of what is needed in their respective spheres, but their activities necessarily overlap, and it is cheering to know that there is a good prospect of the Joint Council and the Hospital Officers joining forces. In many respects hospitals are too self-contained and are working too much in the dark in relation to each other. The creation of such a central bureau is an almost essential condition of that coördination which must come before long if the voluntary system is to attain the highest summit of usefulness. Captain Stone favours the establishment of a voluntary hospitals board, and sketches a suggested constitution representative not only of the hospitals themselves, but of the medical and nursing professions and the general public. There remains the large and highly important question of the fusion, in some form or other, of the voluntary and poor-law systems. From every point of view such a fusion is growing urgent. Many of the poor-law hospitals have now reached a high point of efficiency and the building-up process is constant, but the fact that they often have empty beds while the voluntary institutions are not only crowded but have long waiting lists is a weakness which is unbusiness-like, to say the least. The law as to the pauperisation of the inmates of the poor-law hospitals appears to be not quite clear, but, as Captain Stone suggests, the illisability, if it really exists, could be removed by an Act of Parliament of a single clause. Such a step would clear the way, and it is difficult to believe that there could be any opposition to so simple a solution of a serious practical difficulty.

Among other matters, Captain Stone gives a useful analysis of certain contributory schemes which are so rapidly growing in number and strength, and an account of the progress of the movement for providing beds for paying patients. There is, indeed, no aspect of hospital administration and policy which is left untouched in this admirable and comprehensive volume with its many charts and graphs, and an index which is a model of its kind. The book has a preface by Lord Cave and an introduction by Sir Arthur Stanley.

THE FUNDAMENTALS OF HEALTH.

THE address of a popular nature, given annually before the British Medical Association in memory of Sir Charles Hastings, was delivered at the House of the Association on Wednesday evening by Sir George Newman, Chief Medical Officer to the Ministry of Health, Lord Cozens-Hardy presiding. It proved, as might have been anticipated, a succinct exposition of an enormous subject, in which great questions were dealt with simply and long stories arranged in useful perspective and with due proportion. Especial stress was laid by Sir George Newman on the great rise in the national health in the nineteenth century accompanying notable advances in scientific discovery. He described the relation of these scientific advances to the health and happiness of man as reading like a fairy romance, and proceeded to summarise the tale of nature and nurture in terms of science. "We must not expect," he said, "to apprehend either the science or the practice (of medicine) from hucksters' tips or from the 'bits and bobs' of propaganda in an advertisement of a patent medicine. We must learn to look upon the whole business as a science, concerned with no less a subject than the evolution of man, governed by the immutable laws of the universe, and demanding from us patient learning, vigilant understanding, and strict obedience. For the penalty of the court for disobedience of the laws of Nature is a degeneration of type or an earlier death sentence." Of the advance of medicine which had accompanied the great scientific advance he said that six things, the Darwinian hypothesis counting as one, had given the world a wholly new outlook upon disease and its control, and fresh powers for the relief of suffering, and the prolongation and betterment of life; the remaining factors he gave as the knowledge of physiology derived from the work of John Hunter, the discovery of anæsthetics, the recognition of the causes of infection following on the labours of Pasteur and Koch, the application of that recognition by Lister in the shape of antiseptic surgery, and the resulting development of preventive medicine. Wise remarks on food and feeding, on the value of fresh air and sunlight, of exercise and rest, and of personal cleanliness followed, and led up to a public appeal for the organisation of good health by the community. The purpose of preventive medicine being to improve environment, to develop capacity, and to reduce disease the main lines of policy to this end become Everyman's duty.

SEX EDUCATION.

THAT thorny and difficult subject of sex education has been engaging the attention of the British Social Hygiene Council. We hope they may make some progress in clarifying a situation which presents itself so differently to persons of equal knowledge, integrity, and common sense. We have, on the one hand, those who after much consideration and experience still sincerely adhere, or even desire to return, to the older view that knowledge of sex and sex relationships is best picked up anyhow—"in the gutter" as Dr. Clendening would say. And their opinion is, we understand, to some extent supported by experience of the attempt to teach young and youngish children the truth about sex; the process has not everywhere proved as beneficial or as helpful as its advocates hoped. The plain truth is, of course, that it is quite impossible to get any real understanding of sex into those who have never experienced its consequences. The facts and mechanism of generation can be made the subject of instruction, but to try to explain what passion is to those who have had no chance of knowing for themselves, or what falling in love means to those who have never had the luck to do it, is likely to be as unprofitable as expounding Rembrandt to the blind or Beethoven to the deaf. A knowledge of the anatomy and physiology of males and females is a trivial part of the sexual problem; whether it will help people to solve the really important matters of sexual relationships is on the whole doubtful, and anything it may do in this direction is negligibly small and possibly more than counterbalanced by the evil of rousing a curiosity which may well be left dormant as long as may be. Such, briefly, are some of the considerations put forward by those who would deal with sex education along the broader lines of teaching reticence, restraint, and self-respect. On the other hand is another body of equally sincere and knowledgable opinion, more vocal because it is less conservative, which believes and preaches that the solution of the troubles which wait on sexual maturity lies in frank discussion and knowledge as complete as it may be made. It is, indeed, difficult to say why such a proposal, axiomatic for most human activities, should cease to be properly applicable in this field alone, and it is easy to understand why, made in general terms, it obtains so much assent as it does. But it is evidently felt

that this way of looking at the sex question would be immensely strengthened if there were some objective experience in its favour. The way towards such a trial has been prepared already to a considerable extent. Young adults of both sexes are now often willing, and sometimes anxious, to discuss the sex relationships of men and women with a frankness and freedom which may well make any older people who happen to be present wish they were out of the room. It remains to be seen whether, armed with so much forethought and foreknowledge, they make a better job of it than their Victorian ancestors. They seem to have a better chance; it will be extraordinarily interesting to see the result. It is tempting to suggest that some sort of experiment might be made by making something of a specialty of sex education at some colleges and having none at all at others, and then seeing how the two groups of students turned out in later life. But it is very difficult to simplify the variables to an extent which would justify the experimental method and give an unequivocal answer. Pastors and masters are always apt to forget that their pupils learn at least as much from one another as from their formal instructors, and we are bound to doubt whether any such trial would be really worth making, except under conditions of complete institutional seclusion. Meanwhile we hope that most young children nowadays learn the facts about generation and pregnancy as they learn what happens to the food they eat and how their blood goes round their body. But what best to do with adolescents and young adults is a speculative problem; they will probably go very much their own way whatever wisdom experience holds out to them.

DIETS OF LOW RESIDUE.

MOST text-books on diet give little definite information about the amount of fæcal residue left by different foods, so that the construction of a low residue diet is often based more on opinion than on fact. Such a diet may often be used with advantage after operations on the rectum and anus in order to postpone defæcation and save the patient from pain and discomfort when the bowels are first opened. It is also recommended in the treatment of some forms of diarrhœa and constipation. At the Mayo Clinic an attempt[1] has recently been made to find out the amount of residue from various foods so that definite data may be available. Experiments were made on dogs in which the last 25 cm. of the ileum had been resected, together with the whole of the colon to within 6–10 cm. of the anus, the free ends of the ileum and colon being anastomised. These animals were fed once a day with single foods and fæcal specimens were collected at hourly intervals for eight hours; on the following day any further material found on the floor of the cage or in the rectum was collected and analysed. Gelatin, cane-sugar, dextrose, hard-boiled egg, meat, liver, rice, and cottage cheese were found to give the least moist residue, while the lowest dry residues were seen with dextrose, cane-sugar, gelatin, liver, meat, bread-and-milk, lard, and butter. The largest dry residue (86 per cent.) was given with raw egg albumin, whilst other high residues were obtained from potatoes, raw bananas and apples, and lactose. The experiments suggested that less material is carried into the colon if the diet is kept fairly dry, and that milk should not be given when no movement of the bowel is required. A large residue is left in the terminal ileum after taking this food, which may account for the fact that a milk diet is badly borne by many patients. The Mayo Clinic investigators wish to bring this finding to the attention of the medical profession "because there is a tendency on the part of many physicians to prescribe milk and sometimes nothing but milk whenever they wish to give the digestive tract a rest. They are prone to prescribe it also in cases of diarrhœa, although it appears that it is one of the first foods they should interdict. It has been our experience that milk has a bad effect on many persons with diarrhœa, who promptly get well when given nothing but meat or meat with a little starch or sugar." They also call special attention to the indigestibility of raw egg albumin, which is popularly regarded as the last word in easy assimilation. A certain amount of caution is needed, however, in applying these experimental results to human beings, and it should not be forgotten that in an ordinary diet a considerable residue of undigested food may be desirable. It is perhaps noteworthy that many of the figures recorded in these animal experiments agree with those obtained in men and animals whose colon was intact. This supports the current opinion that the colon absorbs little besides water.

[1] Intestinal Absorption: A Search for a Low Residue Diet. By K. Hosoi, M.D., W. C. Alvarez, M.D., and F. C. Mann, M.D., Arch. Int. Med., 1928, xli., 112.

Sir Hugh Rigby has been appointed Serjeant-Surgeon to H.M. the King, in succession to Sir Havelock Charles, who has been appointed Honorary Serjeant Surgeon.

THE Rev. John William Arthur, O.B.E., M.D. Glasg., has been appointed by the King an Unofficial Member of the Executive Council of the Colony of Kenya.

WE deeply regret to announce the death of Mr. Lionel Richard Fifield, surgical registrar and first assistant at the London Hospital. He died in St. Mary's Hospital, Paddington, early on Wednesday morning as the result of a motor accident.

A PAPER on the Treatment of Recent Fractures by Operation will be read by Dr. Charles Scudder, of Boston, before the Section of Orthopædics of the Royal Society of Medicine on Tuesday, April 3rd, at 8.30 P.M. The subsequent discussion will be opened by Sir Robert Jones, Prof. E. W. Hey Groves, and Mr. H. A. T. Fairbank.

Charing Cross, Westminster, and King's College Hospitals are said to have decided against the admission of any further women students. Should they take this step there will remain only two hospitals in London open to women—the Royal Free and University College. The entry of women to the latter school is limited to 12. It is estimated that there are at present in London 600 women students, about half of whom are studying at the Royal Free. Final decisions on the proposed change have not been reached, and at a meeting of the Senate of the University of London on Wednesday last Mr. Walter Spencer and Dr. Graham Little, M.P., put forward a resolution calling for an inquiry, the result of which was not known when we went to press.

As we have already announced, a conference on rheumatic diseases will be held at Bath on Thursday and Friday, May 10th and 11th, under the presidency of Sir George Newman. The subjects for the three sessions will be the social aspects, the causation, and the treatment of rheumatism, and the congress will deal both with the acute rheumatism of children and with the arthritis and fibrositis of adults. Those who wish to take part are asked to send their names to Dr. Vincent Coates, the hon. medical secretary, 10 Circus, Bath, before May 5th. Special concessions have been made by the railway companies and hotels, and it is stated that the Ministry of Health and the Scottish Board of Health will look favourably on applications for the payment of expenses to representatives of local authorities. The annual meeting of the Balneological Section of the Royal Society of Medicine will be held at Bath on Saturday, May 12th, and members of the conference on rheumatic diseases will be invited to witness demonstrations of treatment by physicians of the Royal Mineral Water Hospital on that day.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

THE TREATMENT OF HEAD INJURIES.

II. Conservative and Operative Measures.*

In the stage of reaction from concussion the patient is apt to be extremely irritable, seeking to get out of bed. His bed can be put against the wall and the bed-clothes may be firmly pinned down, but other forms of mechanical restraint should be avoided, as they only tend to increase the irritability. Skilled nursing does much to control a patient in this stage, and it is important to remember that irritability is often in part produced by a full bladder or full rectum. The room should be darkened, for there is great photophobia.

Morphia should at all costs be avoided; it depresses the respiratory centre, sometimes excites the patient, and may mask a relapse into unconsciousness. For the severe headache that always accompanies recovery of consciousness potassium bromide and chloral hydrate may be given in large doses by the mouth (āā grs. xx. every four hours) or by the rectum (in twice this dose), whilst hypertonic salt solution is of great value.

Hypertonic Salt Solution.—The administration of hypertonic solutions of salt forms a definite recent advance in the treatment of head injuries. As was originally shown by Weed and McKibben, the salt promotes resorption of cerebro-spinal fluid and thus lowers the intracranial pressure. It is used in head injuries to combat the rise of intracranial pressure that invariably follows the injury, and it has proved of great value in relieving the headaches and irritability which are associated with that rise, and in lessening the stupor produced by cerebral œdema. For mild cases 6 oz. of a 25 per cent. solution of magnesium sulphate can be run slowly into the rectum twice a day, fluids by mouth being at the same time restricted. If the magnesium sulphate is not retained in the rectum it can be given by mouth or even by stomach-tube. It is surprising how little diarrhœa is produced by large doses of the drug. In severe cases 70 c.cm. of a 15 per cent. solution of sodium chloride, or a similar amount of 50 per cent. glucose, can be given slowly by the intravenous route. The glucose must be chemically pure. In using sodium chloride care must be taken that the solution is injected only into the vein, for if any escapes into the subcutaneous tissues it is apt to produce local necrosis.

Lumbar Puncture.—Another method of reducing intracranial pressure in head injuries is to withdraw cerebro-spinal fluid by lumbar puncture every two hours. The fluid should be withdrawn slowly and the amount to be removed should always be controlled by manometric readings. The method is open to the objection that it disturbs the patient considerably, and for this reason, whenever possible, the use of hypertonic salt solutions is to be preferred.

Treatment by Operation.

1. *Compound Fractures of the Vault.*—Open wounds call for immediate treatment in order to prevent infection, which may give rise to meningitis, extradural or cerebral abscess, or osteomyelitis of the skull. As soon as his condition permits the patient is removed to the operating theatre. The scalp is shaved for a wide area around the wound and is carefully cleaned with antiseptic. Local anæsthesia (a solution of 1 per cent. novocaine) should be used whenever possible.

If the edges of the wound are dirty they should be excised. All fragments of dirt and hair are removed and the underlying bone is carefully examined. A fissured fracture requires no surgical treatment, and when the wound has been thoroughly cleaned the scalp may be closed by primary suture. On the other hand, if there is the slightest overlapping of the edges of the fracture, a small trephine hole should be made so that the under surface of the fracture may be examined. The reason for this precaution is that at the moment of injury fragments of dirt may be pressed in between the broken edges of the skull and may become entrapped between skull and dura after rebound of the bone. Areas of bone which are obviously depressed should be elevated, but first it is necessary to get a good exposure so that the process of elevation may be carried out under direct vision. This precautionary measure is necessary because dislodgement of a sharp edge of bone may damage the blood-vessels of the cerebral cortex and dura, and thereby occasion severe hæmorrhage. All dirty fragments of bone should be removed. The osteomyelitis of the skull, which may develop if this procedure is neglected, is apt to be a most intractable condition.

The dura is then inspected. If intact, it is on no account opened; if it has been torn, the underlying brain is examined, fragments of clot and dirt are gently removed, and the dura is closed, a fine rubber drain being placed on its outer aspect. It is usually possible to remove the drain within four or five days. After operation for head injuries, the patients, being still in a condition of irritability, often seek to pull off their bandages. It is therefore advisable always to reinforce the soft dressings with a bandage of starch or plaster-of-Paris.

Antitetanic serum should be given at the time of the operation.

2. *Simple depressed fractures* should be elevated within a few days of the injury, because if left they are liable to produce intractable epilepsy. In children they can easily be detected by palpation of the head; in adults, however, they may be closely simulated by hæmatoma of the scalp. When the diagnosis is in doubt it is well to remember that simple depressed fracture is uncommon in adults, so that an apparent depression of the head over which the skin is intact is in all probability a depression in the centre of a hæmatoma. The diagnosis, never immediately urgent, can always be settled by good stereoscopic skiagrams.

To elevate a depressed fracture a scalp-flap, erring on the liberal side, is turned down over the depression. Elevation of the bone should be carried out gently, for it is often followed by sharp hæmorrhage from the underlying meningeal vessels. The bone should be replaced.

3. *Relief of Cerebral Compression.*—When, in cases which have shown the "lucid interval," the intracranial pressure is mounting in spite of hypertonic solutions, and operation has thus become necessary, the question arises as to the situation and manner of exploration. Osteoplastic operations are rarely required. Having regard to what can be achieved by operation, and recognising the need of reducing operative interference to the minimum, it may be said that all we are capable of doing can be done through a simple subtemporal decompression. The side to be explored is determined by the neurological signs. Inequality of the pupils is particularly valuable in this connexion, for experience has shown that, if one pupil is dilated and fixed while the other is contracted, exploration should always be made on the side of the dilated pupil, even in the presence of apparently contradictory paralytic signs. There should, however, be no hesitation in exploring both subtemporal regions in doubtful cases.

Through a linear incision in the direction of its fibres the temporal muscle is divided and retracted. When the underlying bone is removed blood-clot may be encountered, resulting from that comparatively rare condition, rupture of the middle meningeal artery. The clot is removed (suction is the best method) and the artery, if still bleeding, is stopped

* Part I., on General Management, appeared last week.

by means of a silver clip or by bone wax. Whether extradural clot has been found or not the dura should be opened. Clot may be encountered on the surface of the brain and should be gently removed. More often, on opening the dura, no clot is found, but there is an escape of blood-stained cerebro-spinal fluid in unusually large amounts. In this type of case there is presumably a severe cerebral œdema and possibly some disturbance of the mechanism of absorption of cerebro-spinal fluid. These cases usually do well after decompression.

4. *Cerebral Contusion.*—Whether he be unconscious or not, a patient who shows persistent localising signs, such as hemiparesis, astereognosis, or aphasia, should be treated by operation. These signs usually indicate a circumscribed area of cerebral contusion. By decompression at or near the site of contusion the process of recovery is hastened and probably rendered more complete. Usually a subtemporal decompression on the corresponding side suffices to relieve the symptoms of contusion, and it has the advantage over decompression at the site of contusion that the resultant defect in skull and dura is protected by muscle, and is therefore less liable to disturb the patient in after life.

Prolonged Rest.

In all head injuries that have been severe enough to produce distinct concussion it is of the utmost importance that the patients should take complete rest in bed for two or three weeks, or even longer after the accident, according to the severity of the original injury. By so doing they provide the right conditions for repair of the injured brain and run the least risk of developing distressing and debilitating sequelæ.

HUGH CAIRNS, M.B., B.S. Adel., F.R.C.S. Eng.,
Assistant Surgeon to the London Hospital.

Special Articles.

MEDICAL RESEARCH COUNCIL.

ANNUAL REPORT FOR 1926–27.

(*Continued from p. 306.*)

IN a previous notice the sections of this report dealing with problems of the circulation and of nutrition were briefly summarised. We have published in our columns[1] accounts of the research into the alkaline treatment of gastric and duodenal ulcers, carried out by Prof. H. MacLean and Dr. I. Jones at St. Thomas's, and into the effects of the endocrine glands on menstruation.[2] Experiments at St. Bartholomew's on the blood in ammonium chloride acidosis have shown that a change in the hydrogen-ion concentration accompanies changes in the carbon dioxide content and capacity. Among the very large number of other subjects dealt with by various investigators only a small proportion can be mentioned.

Problems of Child Life.

Over 80 per cent. of all infants born in the burgh of St. Andrews are being kept under regular supervision, and the coöperation of the parents is described as "remarkable." It is thus possible to study the relation of environment to the physical and nervous disorders of small children. An investigation into the intelligence of children attending the Royal Hospital at Glasgow has revealed arrested development in most of the cases of encephalitis, with a steady fall in the mental ratio. It failed, however, to show any definite correlation between intellectual deterioration and motor disturbances or changes in character.

At the Children's Hospital, Birmingham, work is being done on the blood chemistry and bone changes in cœliac disease and renal infantilism. The primary cause of the bony deformities in the latter condition seems to be the inability of the kidney to excrete phosphate properly, and treatment by ultra-violet light aggravates the disorder. In cœliac disease, on the other hand, there is poor fat absorption and hence poor supply of vitamin D, with faulty absorption of calcium and phosphorus from the bowel. Ultra-violet light will cure the bony deformities, even on a fat-free diet. Dr. H. A. Harris, working at University College, London, has found that transverse striations occur in the long bones of non-rachitic children after acute illnesses, and mean no more than a cessation of growth from some cause or another. They should, therefore, not be used as a test for the antirachitic properties of foods. For the purposes of life insurance and medico-legal inquiries these lines may be of great value as a record of the past illnesses of an individual. Dr. E. W. Fish, at the same institution, has found a fundamental difference between the teeth of the dog and those of the monkey. The enamel in the dog is freely irrigated with lymph, while that of the monkey is wholly inorganic except for the lamellæ. It may be that this accounts for the immunity of the dog to caries.

Organs of Excretion and Secretion.

Numerous workers are investigating the toxæmias of pregnancy. Evidence has been obtained that alkalis can prevent the onset of anuria and protect the kidney under conditions when nephritis commonly occurs. It is now possible to select the cases of nephritis in which the alkali treatment is likely to be successful. In the course of work at Cambridge under Mr. J. B. S. Haldane, it has been shown that concentrations of magnesium which are optimal for kidney tissue are poisonous to brain tissue, and that the high concentrations found in the blood in kidney disease are secondary to the uræmia. The progress of more than 10,000 men who contracted trench nephritis during the war has been studied; one of the most striking results is the frequency with which the original condition has cleared up, leaving behind it some cardiovascular impairment with high blood pressure.

Prof. V. Korenchevsky has continued at the Lister Institute his attempt to isolate the active principles of the testes and prostate. Difficulty has been found in the unexpected presence of large quantities of insulin-like substances in the testis. The results obtained indicate that active substances are present in both lipoid and protein-like fractions of the sexual glands. It has been found that a parathyroid extract very active in increasing the blood-calcium, produces a persistent decrease in nitrogen metabolism, thus suggesting that parathyroid hormones and insulin act similarly upon nitrogen metabolism, and antagonise the thyroid. Further attempts have been made at Sheffield to control the symptoms of hyperthyroidism by a low diet. Promising initial results unfortunately proved inconsistent. Dr. G. Scott Williamson and Dr. I. H. Pearse are continuing their researches, which tend to establish a true secretion of thyroid hormone by way of the lymphatic vessels as distinct from a storage mechanism in the alveolar chambers. The former secretion contains no iodine and is the intoxicating factor in Graves's disease, while the colloid material contains thyroxin. The Joint Committee of the Council and the Obstetrical Section of the Royal Society of Medicine have decided definitely that there is no value in pituitary extract as a means of inducing labour. It generally shortens the first stage and always shortens the second stage, but has no effect on the third stage of labour. The committee appointed to investigate synthalin[3] found that it could not be regarded as a substitute for insulin, but that it deserved further investigation. It seems to lower blood-sugar by a process differing fundamentally from that of insulin.

[3] THE LANCET, 1927, ii., 517.

Diseases of Animals.

Dr. A. S. Griffith has found that the bovine bacillus is the chief cause of tuberculosis in domestic animals, but that avian bacilli can be transmitted to mammals. Dr. C. Todd has found the path of infection of fowl plague and a means of protecting the birds by immunisation. Studies have been made of the immunity reactions to the virus of enzootic encephalitis (Borna disease) of horses, cattle, and sheep, and the animals have been successfully immunised. Mr. G. W. Dunkin has investigated Johne's disease and prepared a double intradermic diagnostic test, of which satisfactory reports have been received from veterinary surgeons. A method of immunising ferrets against distemper has been found, and many attempts made to extend this to the protection of dogs. While the work is not yet ready for distribution, the laboratory results are very hopeful.

Tuberculosis and Cancer.

The value of blood sedimentation and nuclear index tests as indices of clinical progress in tuberculosis has been confirmed. Blood platelet counts have shown that in surgical tuberculosis, as in phthisis, a thrombocytosis goes pari passu with severity of disease. Plasma becomes a more favourable culture medium for the bacillus when the blood platelets have been removed by filtration. The double intradermal test is steadily replacing the subcutaneous for detection of the disease in cattle.

Dr. Gye has continued his research into the "specific factor," and has found that tissue ferments play a large and sometimes decisive part in nullifying experimental work. The rapid loss of infectivity of filtrate with incubation is due in part at least to the destruction of proteins by a proteolytic ferment. The work of Rous has been repeated, extended, and confirmed. The results tend to show that filtrates of the mammalian tumours tested contain an antigen of extrinsic origin which gives rise in immunised animals to an antibody which, with the addition of complement, neutralises active filtrates of the Rous tumour. Mr. Dick in Edinburgh is investigating the cancer-producing action of coal tar on the alimentary canal, and has studied the actions of sodium tetraiodophenolphthalein, and its dangers in radiography. Mr. Leonard Hill has found no support for the common statement that diet influences the incidence of cancer. A diet of grain and green food gives no protection to mice. Cancer increased in successive generations, rising in female mice from 25 per cent. to 50 per cent.

Ultra-violet Light and X Rays.

Observations at Hampstead have shown a very close inverse relation between the ultra-violet radiation recorded by the acetone blue method and the smoke pollution. On hazy sunny days there may be great brightness when the ultra-violet readings are low. The shortest ultra-violet wave-length seems to be above 3000 A.U., and it must be the longer waves of sunlight that produce vitamin D from ergosterol and flush the skin, although shorter waves from artificial sources act in this way. The great superiority of the long-flamed arc over the Finsen short-flamed carbon arc in erythema-producing rays has been demonstrated. While hæmolysin and cytolysin are destroyed by the longer rays neurotoxin is destroyed readily by short rays, and antivenin is very resistant. Dr. L. E. H. Whitby, at the Middlesex Hospital, has found that the gamma rays of radium are highly bactericidal in the presence of calcium phosphongstate. At the Cambridge Research Hospital it has been found that 20–25-hour embryos can recover from the effects of X rays, while older ones with an active circulation cannot. Isolated tissue fragments, however, from six-day embryos grow actively in culture after radiation. The death of the tissues is due to the inhibition of gaseous exchange due to the action of the rays on the circulatory system.

Pharmacology.

A new base, "spermidine," related to but simpler than spermine, has been isolated and identified and adds yet another to the class of constant tissue constituents for which no physiological function can yet be even suggested. The peculiar peptide "carnosine" caused unexpected difficulties in a chemical investigation of muscle, and the successful solution is expected to throw light on the whole subject. A large quantity of carnosine has been prepared for examination of its properties and reactions.

Some 50 synthetic compounds of organic substances related to dyes have been prepared and tested for trypanocidal activity. The work has suggested a method by which a number of organic nuclei may be tested quickly for their potential value as starting-points in the synthesis of trypanocidal remedies. Observations have been made on the double nature of the mechanism which cures trypanosome infections. It appears that first some of the parasites are killed by the drug and that thereby an immunity response is produced which leads to the destruction of the rest. A curative dose of a trypanocidal agent may be rendered ineffective when a subtherapeutic dose of some other substance is administered shortly before.

Sir Almroth Wright's studies have shown that it is necessary, for bactericidal tests, to pack the corpuscles as far as possible free from serum. The application of a procedure devised for this is giving good results. It has been found that the acquired potency of the blood in its defence against streptococci can be considerably prolonged by using the least toxic arsenical compounds and by spacing the doses so as to maintain adequate concentration. The white corpuscles of patients suffering from severe streptococcal infections have been found to be much more sensitive to the toxic action of arsenical compounds than those of healthy persons. Mercurochrome has not been found to confer bactericidal power in animals, either upon the blood or on the bile. Dr. Todd has found no evidence of a relation between the virulence of hæmolytic streptococci and their capacity to produce a filtrable toxin.

A new gold compound of cystein has been formed from a normal constituent of tissue proteins, and so offers possibilities of introducing gold in a more natural vehicle.

Routine work on biological standards and assay has continued, and during the year over 4000 cultures from the national collection of type cultures were distributed, and more than 200 new strains were added. The output of standard agglutinable cultures and sera was four times greater than that for 1920–21.

Optics and Vision.

The department of applied optics has constructed two new microscopes, giving better facilities for the rapid repetition of observations, and a new type of reflecting condenser system has been designed to reduce the length of exposure in ultra-violet dark ground photomicrography.

Dr. H. Banister at Cambridge has shown that visual acuity is of less importance in selecting a good rifle shot than might be expected. Right-eyedness, however, is of great importance, and other tests for particular kinds of manual muscular control and coördination will detect the man to choose. It has been shown that a flicker as slow as eight per second does not impair visual acuity or colour appreciation. A biochemical study at St. George's Hospital has suggested that the aqueous fluid in the eye is formed by dialysis from the blood.

Physiological Investigations.

The katathermometer has been made available for use as an instrument of precision for measuring ventilation in warm and humid mines or factories, thus meeting a long-standing need of ventilating engineers. Dr. J. A. Campbell has shown that acclimatisation to low oxygen pressure is due to the body tissues, particularly the heart muscle, becoming tolerant of a low pressure in their immediate environment. He found no evidence in favour of the common view that the local oxygen tension in the tissues is restored nearly to normal during acclimatisation, nor did he find any close relationship between power to

increase the red cells and hæmoglobin or between the carbon dioxide tensions in the tissues and powers of acclimatisation, so that breathing cannot play the main part in the process. The heart seems to be the chief organ concerned; with insufficient oxygen its muscle degenerates. The underlying principle advanced by Dr. Campbell is that the body is unable to prevent a large rise of internal oxygen tensions under exposure to high oxygen pressure in the air, just as it is unable to prevent a large fall of oxygen tension in the tissues under exposure to low oxygen pressure in the air.

Mr. P. Eggleton has continued his study of "phosphagen," a constituent of muscle, which has been isolated as a barium salt from rabbit muscle and shown to contain creatine and phosphoric acid in equimolecular amounts. It breaks down in a muscle in contraction producing inorganic phosphate and is resynthesised during recovery in the presence of oxygen. This work clears up uncertainties about the relative places, in the chemical machinery of muscle contraction and relaxation, of carbohydrate and phosphate, and adds a new link between the functions of muscle and the presence of creatine. Phosphagen is apparently related to the velocity of contraction.

Intestinal Flora.

Mr. C. Dobell and Dr. P. Laidlaw have obtained every stage in the development of the *Entamœba histolytica* in artificial culture. It has been shown that the amœbæ cannot survive at ordinary temperatures for more than three days, but the cysts can live and remain infective to man for 37 days Emetine has been shown to have a specific toxic action in cultures on both human and simian strains. The entamœba can be transmitted from man to the monkey. One strain has been propagated in the department for three years, and has lost its original infectivity for kittens though not for monkeys, and has also lost its power of engulfing red corpuscles. Miss Bishop has shown that neither increase nor decrease in oxygen pressure, within the limits tolerable by a monkey, has any lethal effect upon intestinal protozoa.

Dr. L. S. Davidson, of Edinburgh, has devised a method for quantitative estimation of the chief groups of intestinal bacteria by which the differences of intestinal flora in health and disease can be tabulated. He believes that in the most chronic infections the cause is no new organism, but an increase in numbers or a change in site of the organisms normally present. In pernicious anæmia all organisms are enormously increased in number and there is a huge count of *B. welchii*. The toxæmia of intestinal obstruction seems to be probably due to this organism.

MEDICINE AND THE LAW

Dr. Alcock's Unsuccessful Appeal.

"A JURY," said Lord Justice Scrutton last week, "is rarely a good tribunal to decide actions which depend on professional skill." This important dictum was delivered during the judgment dismissing Dr. Alcock's appeal from the verdict of heavy damages awarded against him at Gloucester Assizes last December. The facts of the case will be remembered. A little girl, 8 years of age, fell off a donkey and broke her left arm above the elbow. She was conveyed ten miles in a motor-car to Gloucester where the limb was set in the doctor's surgery and she then went into a nursing home in Gloucester. The case alleged against Dr. Alcock was that he bound up the arm in a bent position without having got the fractured bone into complete alignment, thus producing a condition in which the arm muscles deteriorated. As Dr. Alcock was able to show, he had adopted the most approved surgical practice. An X ray photograph was taken before he began treatment; while he was manipulating the arm the X ray apparatus was used to throw the reflection of the bone upon the screen so that he could see exactly what he was doing. When he had finished the manipulation and bound up the arm, the radiologist reported that th X ray photograph showed a perfect reduction of th fracture. In these circumstances Dr. Alcock watche the arm subsequently to see that the circulation wa not impaired; as soon as he detected that this ha occurred, he loosened the bandages and endeavoured though without success, to ward off worse symptoms For the plaintiff it was said that faulty setting an subsequent negligence established Volkman's cor tracture; as this resulted in permanent deformit the child, who was stated to be a particularly promisin musician, would be unable to follow the professio of music. Impressed by this fact, presumably, th jury awarded the large sum of £2150 damages. Dr Alcock went to the Court of Appeal and asked fo a new trial, complaining that Mr. Justice Shearman summing-up was not adequate and that he ha overlooked the fact that the doctor had followed th most approved surgical practice; the judge, it wa contended on Dr. Alcock's behalf, had never told th jury that Dr. Alcock was entitled to rely on what th radiologist told him.

Lord Justice Scrutton's observations deserve clos attention. The Court of Appeal was obliged t dismiss the application for a new trial because th law of the land has placed juries in the position o deciding these issues of professional skill or negligenc and, unless it could be said that there was no evidenc whatever to support the jury's verdict (which wa not suggested), it was impossible for the Court o Appeal to interfere. "I do not profess for one moment, said the Lord Justice, "that this case is a satisfactor one." The action was one for professional negligenc "The consideration of the margin between wha would be an error of judgment (which is not actionable and a departure from the degree of professional ski which a professional man practising for reward hold himself out to exercise is very difficult to explain t the jury and very difficult for them to follow. . . It might very often happen that the judge woul not feel very happy about the verdict of the jury and the Court of Appeal also might not be very happ about a verdict against a professional man, but, we were to grant a new trial, the case would have t go back again to the same tribunal"—i.e., a jury In this case, said Lord Justice Scrutton, ther was evidence before the jury on which they, properl directed, were entitled to decide either way; it wa impossible for the Court of Appeal to interfere wit the verdict although the members of that Cour might have come to a different conclusion.

If the natural sympathies of a jury towards a littl girl of 8, whose potential prospects as a professiona musician are unhappily marred by an accident to he arm, are to be translated into the award of heav damages against a medical practitioner who ha followed the most approved surgical practice, the we really seem to be approaching the position i which a surgeon must be taken to guarantee the succes of every operation he undertakes. Lord Justic Scrutton's judgment makes it clear that the verdic against Dr. Alcock is far from commanding his whol hearted assent. There is something wrong with th system when such a verdict can be enforced agains a professional man. The medical profession has ofte had occasion to protest against questions of pro fessional skill being left to the arbitrament of a jur entirely devoid of technical knowledge. Lord Justic Scrutton's opinion of the unsuitability of a jury a the tribunal in such matters will strongly reinforce th view of the profession that the present position intolerable.

Patent Rights in Therapeutic Manufactures: The Nee of Novelty.

The claim of Sharp and Dohme (an America company, incorporated in New Jersey) against Boot Pure Drug Company, raised highly technical issue but also illustrated valuable principles of patent law The plaintiffs brought their action originally befor Mr. Justice Astbury, claiming that they were entitle

to Letters Patent (No. 219,922) for a method of making new alkyl resorcinols of high therapeutic value, particularly valuable as a non-toxic germicide; they claimed that the defendant company had infringed their patent. The defendant company answered that the patent was invalid for want of novelty and subject matter; that the methods described in the plaintiff's specification had been published before the date of the patent; or that the prior publication had indicated methods to be adopted for obtaining homologous alkyl resorcinols higher than those hitherto obtained. It was a question to some extent of how wide the plaintiff's specification might be. Their process was based on information contained in two previously published papers—those of Johnson and Lane (in the American Chemical Society's Journal of 1921) and of Clemmensen in 1913. Evidence by Sir William Pope and Mr. Ballantyne indicated that the reductions disclosed by Clemmensen were of such general value that, if used, they would probably result in the product for which the plaintiffs claimed a patent. It seemed clear that, if the plaintiffs had a valid patent, the defendants could not deny infringement. They had made and sold n-hexyl resorcinol made by a method indicated in Johnson and Lane's paper. Mr. Justice Astbury held there was no subject matter in the patent; he also held that the patent was invalid because of anticipation. In his judgment it appeared that the foundation of the process was laid in 1913; the only thing left to be done was to verify the anticipation of the earlier chemists. Verification of an earlier statement is not a ground for a patent grant. The plaintiffs took the case to the Court of Appeal, but their appeal was unanimously dismissed by a Court consisting of the Master of the Rolls and Lord Justices Sargant and Lawrence.

The subject matter of the privilege granted by a patent must involve, as is observed in Halsbury's "Laws of England," discovery and a new art. "An invention," said Lord Justice Lindley in 1892, "is not the same thing as a discovery; when Volta discovered the effect of an electric current from his battery upon a frog's leg, he made a great discovery, but no patentable invention; again, a man who discovers that a known machine can produce effects which no one before him knew could be produced by it, may make a great and useful discovery, but, if he does no more, his discovery is not a patentable invention." The subject matter of a patent is something for the sole working or making of a manufacture, but the manufacture must be something new and, further, it must not have been used by others at the time when the patent is granted. The reason is clear. The inventor must be encouraged but the justification for his monopoly is the benefit of the public. If his invention is not new, the public gets no benefit. Famous men like Lord Kelvin have been heard to express the view that our system of protecting discoveries by monopoly has done as much harm as good. If medical research were to be commercialised, the public benefit would be diminished. Judicial insistence that the element of newness should be present if patent grants are to be valid is well founded not only in law but in public advantage. Lord Danworth in the case under discussion confirmed Mr. Justice Astbury's view that no inventive step had been taken; there had been only verification of previous researches, coupled with the ordinary skill that a chemist could be expected to provide and supply. It is matter for general congratulation that the English bench can produce judges capable of mastering the extremely technical details of patent cases. Specialists like the late Lord Moulton may be rare, but such judgments as that of Mr. Justice Astbury are the more frequent judgments of Mr. Justice Tomlin in patent matters are supremely competent.

Dangerous Drugs Register.

One object of the Acts and regulations dealing with dangerous drugs is to make it possible to trace a purchase. For this purpose the medical practitioner is obliged to keep a register and to enter his purchases therein. At the West London Police-court on March 16th a doctor was charged with failing to enter in the register required to be kept for that purpose certain purchases of dangerous drugs—namely—morphine sulphate and diamorphine hydrochlorate. It was stated that a detective-inspector had occasion to interview the defendant doctor about prescriptions containing heroin and cocaine supplied to two women patients. Purchases had been made from wholesale chemists in October and January last, but the purchases had not been entered in a register as required, though the defendant was able to produce a book showing a list of prescriptions. On behalf of the medical practitioner it was mentioned that he had practised for 14 years in Jersey and was unaware of the details of the Dangerous Drugs Regulations operating in this country. It was not suggested that he had been guilty of any illicit traffic in drugs. The magistrate, Mr. Marshall, imposed fines amounting to £21 with £3 3*s.* costs.

THE HARVEY TERCENTENARY:

CELEBRATION BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON.

FROM the Royal College of Physicians of London there has been issued a provisional programme of the several functions and entertainments arranged by the College in the course of the celebration of the Harvey Tercentenary; this is issued in advance, so as to give delegates and others early information of a general character. A full and detailed programme will be published in May, and may be obtained then on application at the College. Delegates and guests should send information as early as possible of the number of ladies, if any, accompanying them, in order that the Ladies' Committee may make suitable arrangements for the entertainment of ladies at certain ceremonies where their presence may be impracticable owing to limitations of space. Visitors attending the celebration may give the Royal College of Physicians, Pall Mall East, London, S.W. 1, as their postal address, and letters will be handed to them when they call. They should, on arrival, leave their London addresses with the Secretary of the College.

Provisional Diary.

Monday, May 14th: 11 A.M., Reception of delegates by H.M. the King at Buckingham Palace. 3 P.M., Reception of delegates and distinguished guests by the President of the Royal College of Physicians at the College; presentation of addresses by delegates; admission of honorary Fellows; eulogy of Harvey by selected speakers. 6.30 P.M. for 7 P.M., dinner to delegates and guests given by the Worshipful Company of Grocers at Grocers' Hall, Prince's-street, E.C.

Tuesday, the 15th: 10.30 A.M.–12.30 P.M., demonstrations of recent additions to our knowledge of the circulation by the Royal College of Physicians at University College. A reproduction of Harvey's original experiments will be displayed cinematographically. 1.15 P.M., luncheon to delegates and guests at St. Bartholomew's Hospital (Harvey's hospital), given by the governors of the hospital. 4 P.M.,* tea to delegates, guests, and their ladies at the College, with exhibition of books, manuscripts, pictures, silver, and other objects of interest. 9 P.M.,* conversazione of delegates, guests, Fellows, and their ladies at the Hall of the Worshipful Company of Merchant Taylors, 30, Threadneedle-street, E.C., by permission of the court of the company. The Prince of Wales has graciously consented to be present.

Wednesday, the 16th: In the morning there will be a continuation of the demonstrations at University College, London. 6.30 P.M. for 7 P.M., dinner to delegates and guests given by the President and Fellows of the Royal College of Physicians in the Guildhall of the City of London.

Thursday, the 17th:* In the morning and afternoon there will be a visit of delegates, guests, and their ladies to Oxford, by invitation of the Warden and Fellows of Merton College, of which Harvey was Warden.

Friday, the 18th:* In the morning and afternoon there will be a visit of delegates, guests, and their ladies to Cambridge, by invitation of the Master and Fellows of Caius College, whence Harvey graduated.

* Ladies are invited to those functions marked with an asterisk.

Morning dress will be worn at daytime and evening dress, with orders and decorations, at evening events.

It is hoped, however, that delegates and guests at the afternoon reception at the Royal College of Physicians on Monday, the 14th, will wear academic dress. Throughout the whole week preceding the celebration, including Sunday, the 13th, the Secretary's office will be open daily from 2 P.M. to 5 P.M., so that delegates, guests, and their ladies may call for programmes, tickets for the various meetings and entertainments, and for any other information they may require. It is requested that such calls may be made as early as possible.

Entertainment of Ladies.

Monday, the 14th: Afternoon, visit to Messrs. Peek, Frean and Co.'s model biscuit factory; tea provided. Evening, 9 P.M., Lady Bradford, "At home," at 8, Manchester-square, W. 1.

Tuesday, the 15th: Morning, visit to Royal Mint. Afternoon, visit to Royal College of Physicians (see diary). Evening, conversazione at Merchant Taylors' Hall (see diary).

Wednesday, the 16th: Morning, visit to White Lodge in Richmond Park, to see the pictures, by invitation of Lord Lee of Fareham; drive to Hampton Court Palace.

Thursday, the 17th: Visit to the University of Oxford (see diary).

Friday, the 18th: Visit to the University of Cambridge (see diary).

Other entertainments are in process of arrangement.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

The Simon Commission.

THE arrival of the Simon Commission has focused attention on the lines along which the self-governing institutions will develop, and these have their bearing on the future of medicine in India. Under the present Reforms Act of 1919 medical education and public health are "transferred" subjects—that is, they are dealt with entirely by Ministers of Local Governments. It will be the duty of the Commission to ascertain how far the present system has been utilised to advantage or otherwise since its introduction. Sir Norman Walker's tour in India was undoubtedly a stimulus to medical education here. The formation of a Central Medical Council for India was foreshadowed in his report and a Bill for the formation of such a body was brought before the Central Legislature. As, however, it contained a proposal that hakims, vayds, and other representatives of indigenous systems should sit on the Council, the Bill proved unacceptable. It is a sorry fact that the Reforms Act of 1919 practically overlooked medical and public health matters, and it is difficult to see how under the present Act such a body could be formed for the whole of India. But it is a point which may not escape the notice of the Simon Commission.

The Far Eastern Bureau.

The Advisory Council of the Far Eastern Bureau of the League of Nations has met at Delhi under the Chairmanship of the Public Health Commissioner of the Government of India, Dr. Madsen, of Copenhagen, and Prof. Shiga, of Korea, being among the 14 delegates present. The work of the Bureau is facilitated by the broadcasting of the weekly epidemiological report to the participating Governments. The incidence of epidemic disease in 147 ports of the East is now communicated by wireless to practically every country of the world within a few hours, with the result that quarantine measures can be speeded up and great economy effected. The international programme of plague research agreed on in Calcutta was adopted, and steps were taken to bring the findings of the plague experts to the notice of Geneva.

Proposed Central Research Institute.

The Calcutta Congress has stimulated effort directed to the prevention of disease in India. A committee, headed by Sir Walter Fletcher, has visited Lahore, Kasauli, Bombay, Madras, Ranchi and many intervening stations to examine the scheme for the establishment of a Central Imperial Medical Research Institute for India—to supplement, not to replace those at present existing in Calcutta, Bombay, Madras and Kasauli. The object of such an institution would be the coördination of research work with other countries.

Health Demonstration Trains.

A novel form of medical propaganda is the organisation by some of the railways of scientific demonstration trains. One of these recently toured the Punjab and another Eastern Bengal. The public health exhibits were extremely graphic with posters and advice regarding the preservation of life and health. Veterinary exhibits showed the results of cattle disease, the advantages of prophylactic injections, and the lines on which cow-sheds should be built. The demonstration train in the Punjab attracted 300 visitors in one village near Lahore and Amritsar and 12,000 at Kasur.

Medical Education.

Statements made in one of the official pamphlets issued to the Congress visitors regarding the backward condition of medical education in India have produced some searching of heart among the indigenous practitioners in Bombay. There is no doubt that the Indian student is frequently unable readily to follow conversational English with his English teachers, but the position would hardly be better if he had Indian professors teaching in the English language. It is no doubt at the doors of the schools and the arts faculties of the universities that the blame lies. Secondary education throughout India is at a low level. At the same time there is a strong feeling among the indigenous medical profession that although the General Medical Council should have statutory powers of control over medical education in India, there should be a representative of Indian Universities on that Council. The ideal solution might be for the Government of India to establish a Central Medical Council for India coöperating with, and under, the auspices of the G.M.C. It should not be more difficult to maintain the standard of medicine than that of other professions throughout India.

City Water-supplies.

Calcutta, many years ago, adopted slow sand filters, and is at present engaged in enlarging its water supply from 49 to 75 gallons per head. Madras, Poona, and Bombay have, in the past, delivered unfiltered water from unreserved upland gathering grounds, and this water, on occasions, has been accused of carrying water-borne disease. Bombay takes its supply from large lakes and, up to last month, the water was brought most of the way in open aqueducts. These aqueducts have now been replaced by large steel mains, and the supply is chlorinated. This important improvement was formally opened last month by the Governor of Bombay.

Malaria and Irrigation.

Special interest attaches to the visit to Bengal of Sir William Willcocks, a recognised expert in irrigation. Many parts of the Bengal delta are extremely malarious and it has been pointed out by Prof. C. A. Bentley that this condition is associated with comparative dryness, little or no flooding, and deteriorated agriculture. In Egypt, where the land is well irrigated, and two or three crops brought in each year, there is little or no malaria. If more water could be brought into the dry tracts of Bengal prosperity would be enhanced, crops increased, and malaria very likely diminished. These points have been appreciated before, but hitherto the control of so large a river as the Ganges has been regarded as impossible. Sir William is at present touring the Ganges delta, and while he has not yet pronounced any definite views, it is understood that he regards as possible the damming of the Ganges by a large

barrage, and the distribution of its head waters by old channels to dry areas.

Opium and Ayurveda.

The policy of the Government of India with regard to opium still remains undeclared, as the report of the Committee recently appointed has not yet been published. A certain amount of criticism comes from the Ayurvedic practitioners, who employ opium very largely in their pharmacopœia and who are maintaining strongly that the undue restriction of the sale of opium is not to the interests of the indigenous practitioner.

The late Colonel Cook Young.

The news of the death of Lieut.-Colonel A. W. Cook Young, in a nursing home at Aberdeen on Feb. 7th, came as a shock to his many friends in Northern India, where he was widely known and very popular. He entered the I.M.S. in 1901, and had only recently retired on completion of 27 years' service. The most of his service was spent in military employ, except for a few years before the war, when he was medical officer of health for New Delhi. He saw service in the Tibet expedition of 1903, when he gallantly went to the assistance of a brother officer, attacked by a mad Lama, and sustained a severe scalp wound which nearly cut short his career. He served during the Great War in Egypt and as sanitary officer in Mesopotamia, receiving a Brevet Lieut.-Colonelcy. Cook Young was an enthusiastic polo player in his earlier years, and since the war took up racing, winning many trophies, notably the Army Cup at Lucknow in 1919. He was a fine type of the now extinct regimental medical officer, popular alike with officers and men, and he never took kindly to the station hospital system introduced for Indian troops after the war. A brusque and somewhat abrupt manner covered a kindly and genial nature; his caustic wit was never unkind.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Vital Statistics of the Negro Community.

THE admission, in recent years, of several Southern States to the birth and death registration areas has now opened to the vital statistician a new and promising field. At the suggestion of several negro sanitarians, the Office of Statistical Investigations of the United State Public Health Service in the person of Dr. May Gover has made an interesting preliminary review of the vital statistics of the American negro population.[1] This population has been increasing since 1790, but not so fast as the white population or even the native white population. This, although the mulatto is added always to the negro population. The coloured birth-rate in 1920 was slightly greater than the white—107 to 104. The ratio of negro mortality to white is 1·87 in the cities, 1·49 in the rural areas. Life-tables published for white/negro in various States bring out interestingly the risks at various ages. They show amongst other things that in the Southern States after age 40 the country negro has a better expectation of life than the city white. This is not true in Northern States like Ohio and Michigan. Tuberculosis is the outstanding cause of death in the negro population, being as high as 202 per 100,000 in the Southern Registration States. Cancer, diphtheria, measles, and scarlet fever have all lower rates for coloured than for white. In studying the trends of mortality, the resemblances between the races were found to be more striking than the differences.

[1] Mortality Among Negroes in the United States. Pub. Health Bulletin, No. 174. Washington: Government Printing Office. 1928. 15 cents.

Suggested Revolution in Criminal Procedure.

The proposals put forward some time ago by American psychiatrists, and reported in a previous letter, have found a powerful friend in Governor Alfred E. Smith of New York. The popular Governor has suggested that a State commission, composed of experts in psychiatry and penology, should be charged with responsibility for dealing with offenders after conviction, which would automatically relieve judges of the responsibility of pronouncing sentence. Such a revolutionary change in criminal procedure would involve an amendment to the State constitution. The Governor has recommended to the State Crime Commission that the legislature be asked for funds to make an exhaustive investigation. The main points in the proposal are summarised in the *New York Times* as follows:—

That the jury should determine only the guilt or innocence of the person on trial.

That after a jury has returned a verdict of guilty the power of imposing sentence should be taken from the judge who presided at the trial and given to a special State board to be created by a constitutional amendment.

That the members of this board should include legal experts, psychiatrists, and penologists devoting their entire time to the work and paid as high salaries as any others in State employ—$25,000 a year.

That this board should determine whether a convicted felon should go to a State prison or to an insane asylum; and that it should determine the length of punishment and the extent he may be subject to parole.

The cost of operating the scheme might amount to $1,000,000 yearly, but if successful it should prove a good investment. At any rate it has been warmly welcomed by criminologists and social workers as well as by the National Committee for Mental Hygiene.

The Cost of Funerals.

Many factors, mostly associated with the enterprise of the "morticians," have contributed to make the American funeral an expensive affair. The practice of embalming is almost universal. The average cost of embalming is less than £5, but the result is that the body lies in state often for several days, and this leads to the demand for magnificent coffins which are called caskets. It may account also for the popularity of the watertight caskets which I have seen in profusion at a State Fair, the watertightness being demonstrated in a booth equipped with a large water tank! In wealthy families these luxuries are not a serious factor but in poorer families they lead not seldom to destitution. The problem became serious enough two years ago to lead the Metropolitan Life Insurance Company to appropriate $25,000 for an investigation. A strong committee, including several prominent medical men, was appointed, and they have now issued their report. They find that in estates of less than $1000 more than one half the estate goes on the average into funeral expenses. They blame first the desire of the family for an elaborate funeral based either on convention or in order to "impress the neighbours," and in the second place they blame the lack of organisation in the industry. The latter is already in process of self-improvement and the committee appeals to doctors and ministers to help "ease the burden of burial for those who can least afford to bear it."

Tularæmia in Mice.

Large numbers of sick and dead mice having been found in Contra Costa County, California, a pair of dead field mice were sent to the plague laboratory in San Francisco. Spleen tissue of the wild mice was inoculated into white mice, white rats, and guinea-pigs, all of which developed typical lesions of tularæmia. *Bacterium tularense* was isolated from the guinea-pigs, and its identity confirmed by agglutination with a known serum. This is the first record of the *Bacterium tularense* having been isolated from naturally infected wild mice.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

The Edinburgh Corporation Bill.

LAST week a deputation from Edinburgh met the Secretary of State for Scotland, when the Town Clerk of Edinburgh argued forcibly in favour of allowing the compulsory system to be instituted. Mr. Neville Chamberlain, the Minister of Health, who was present was not persuaded, and said that the Government Whips would be put on when the vote of the House was taken at a second reading of the Bill. At a meeting of the Edinburgh Corporation last Tuesday, however, it was decided to proceed with the Bill. The Corporation have behind them the majority of the local authorities in Scotland and of the medical profession in Edinburgh.

Preservatives in Cream.

The statement of one of your Scottish correspondents in THE LANCET of Feb. 4th to the effect that what had been the law in Scotland under the Food and Drugs Acts is to be enforced under the new Preservatives Regulations, both English and Scottish, has been called "bad law." The brief facts of the situation are: (1) in England regulations authorised the addition of boric acid to "double cream"; (2) there were never any such regulations in Scotland; (3) the Sale of Food and Drugs Acts require that an article sold must be of the nature, substance and quality of the article demanded; and (4) under these Acts no person is to mix any article of food with any ingredient or material so as to render the article injurious to health. In Scotland any producer who added a preservative to cream has all along been liable to prosecution under these Acts; but, as the *Dairyman* states (quite fairly):—

> "If proceedings were launched against the seller under the Sale of Food and Drugs Acts for selling an article dangerous or injurious to health, there was no certainty that he would be convicted. Whether the proportion of boric acid present did in fact render the cream dangerous or injurious to health was a question of fact for the Court, often decided in favour of the defendant."

The condensed statement made in these columns that the prohibition of all preservative in "cream" presumably removes the necessity of proving whether any given percentage of boric acid present does, or does not, render the article injurious to health, is in line with the statement of the *Dairyman*: "After the promulgation of the Amending Regulations in 1916, the Court—in England and Wales—had no option but to convict if 0·4 per cent. was overstepped or if any preservative whatever was present in cream with less than 35 per cent. of fat." Under the Preservative Regulations, England and Scotland have now the same standard, and one of the objects of the Food and Drugs Acts—namely, to keep articles of food as pure as possible—thus receives greater definition.

Anderson College.

Anderson College, founded in 1796 and affiliated to the University of Glasgow some 25 years ago, is remarkable for the wide distribution of its old students, while many pioneers of modern medicine have taken out classes at the institution. Dr. J. D. Comrie, lecturer on the history of medicine in the University of Edinburgh, delivered last week the closing lecture to the Winter Medical Session at the College, in which he made an eloquent acknowledgment of the debt owed by modern medicine to the earliest workers. He showed how many of the fundamental facts of our science had been discovered in the school of medicine at Alexandria 2000 years ago, and how light was thrown upon this work by the publication, 300 years ago, of Harvey's "De Motu Cordis." He referred in his address especially to the work of Thomas Sydenham in relation to the use of quinine in malaria, to the advances in surgery made in Scotland by Peter Lowe and Richard Wiseman before the Listerian era, and to Lister and Macewen as being responsible for all that to-day stands for scientific surgery. At the close of the address the medals were presented to the prize-winners of the College.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 10TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox 347 (last week 365); scarlet fever, 1692; diphtheria 1311; enteric fever, 40; pneumonia, 1663; puerperal fever, 53; puerperal pyrexia, 142; cerebro-spinal fever, 12; acute poliomyelitis, 6; encephalitis lethargica 29; dysentery, 14; ophthalmia neonatorum, 100. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 24 counties:—London, 1; Bedford, 2; Chester, 2; Derby 21; Dorset, 1; Durham, 68; Gloucester, 4; Hertford 1; Lancaster, 38; Lincoln, parts of Kesteven, 1; parts of Lindsey, 3; Norfolk, 1; Northumberland, 11; Nottingham 14; Southampton, 1; Stafford, 13; Suffolk East, 1; Surrey, 1; Warwick, 4; Yorks, North Riding, 13; West Riding, 89; Brecknock, 3; Glamorgan, 25; Monmouth, 29.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board, March 13–14th, was as follows:—Small-pox 11 (2 of them being under observation); scarlet fever, 1587; diphtheria, 2538; enteric fever, 33; measles, 1466; whooping-cough, 147; puerperal fever 13 (plus 9 babies); encephalitis lethargica, 68; "other diseases" 33. At St. Margaret's Hospital there were 15 cases of marasmus and 13 babies (plus 6 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there were 2 deaths from small-pox, 6 (2) from enteric fever, 141 (77) from measles, 13 (6) from scarlet fever, 49 (15) from whooping-cough, 34 (4) from diphtheria, 35 (13) from diarrhœa and enteritis under two years, and 109 (23) from influenza. The figures in parentheses are those for London itself. The deaths from enteric fever outside London were reported from Southend-on-Sea, Worcester, Sheffield and Newcastle-on-Tyne, one each. Of the 64 fatal cases of measles outside London, 7 each were reported from West Ham and Plymouth, 5 each from Tottenham, Manchester, and Sheffield, 4 each from Worcester and Warrington; while the figures in Glasgow and Dublin for the same week were 19 and 5 respectively. Two fatal cases provisionally classified to small-pox were assigned to the county boroughs of Rotherham and South Shields.

The death at Rotherham attributed to small-pox was Dr. William Barr tells us, that of a woman (unvaccinated) 73 years of age, who became ill with the usual prodroma influenza on Feb. 5th. The rash appeared on the 11th she was notified as mild small-pox on the 13th, and removed the same day to hospital. At this time the patient felt quite well and remained so until Feb. 29th, when she had a slight attack of bronchitis. On March 3rd she had almost completely recovered, and, as the rash had practically gone it was contemplated to discharge her on the 8th or 9th. But she collapsed and died suddenly on the morning of March 4th. Dr. Barr was informed by her relatives and by her private medical attendant that she was subject to periodical heart attacks for several years. The death was certified as (1) bronchitis, (2) cardiac failure, (3) small-pox.

CREMATION SOCIETY OF ENGLAND.—The annual general meeting of members will be held at 28, Portland place, London, W. 1, on Wednesday, March 28th, at 3.30 P.M. when the report of the Council for the year 1927 will be submitted.

TEDDINGTON MEMORIAL HOSPITAL.—Lord Dawson recently laid the foundation-stone of this institution, which is to replace the existing cottage hospital. The building provides two wards of 12 beds each and two single-bed private wards for paying patients.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg.-Comdrs. J. Fullarton and G. E. Hamilton are placed on Retd. List with rank of Surg. Capt.

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. G. F. Abercrombie to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Capt. A. J. Beveridge to be Maj.
Lt. G. C. Phipps to be Capt. (Prov.).
E. A. Stroud to be Tempt. Lt.

TERRITORIAL ARMY.

Capt. A. C. Haddow to be Maj.
Capt. (Prov.) R. S. Creed is confirmed in his rank.
Lt. W. H. A. Dodd, from Gen. List, to be Lt.

TERRITORIAL ARMY RESERVE OF OFFICERS.

Capt. F. G. Armstrong, having attained the age-limit, relinquishes his commn. and retains his rank.
Maj. E. Alderson, from the Active List, to be Maj.

ROYAL AIR FORCE.

Flight Lt. J. D'Isney Rear is granted a permanent commission in this rank.
Flying Officer G. S. Strachan is promoted to the rank of Flight Lt.
Flight Lt. D. B. Smith is transferred to the Reserve, Class D, II.
Flight Lt. E. Alston (temp. Capt., Dental Surgeon, General List) relinquishes his temporary commission on resignation of his Army commission.
The undermentioned are granted permanent commissions: A. F. Cook, E. J. Jenkins, and J. Magner as Flight Lts.
L. Freeman and G. S. Strachan as Flying Officers.
Flying Officers J. P. Hederman and E. J. Mockler to be Flight Lts.

INDIAN MEDICAL SERVICE.

Lt.-Col. L. J. M. Deas to be Col.
Capt. (Prov.) W. Lawie is confirmed in his rank.
Col. H. M. Cruddas retires.

COLONIAL MEDICAL SERVICES.

J. B. Kirk, M.O.H., Port Louis, Mauritius, to be Director of the Medical and Health Department, Mauritius. R. P. Cormack, Assistant Bacteriologist, Uganda, to be Senior Bacteriologist, Kenya. N. P. Jewell, Senior M.O., to be Resident Surgical Officer, Nairobi Hospital, Kenya. W. L. Webb, Senior M.O., in charge at Mulago Hospital, Uganda, to be Deputy Director of the Medical Service, Uganda, H. B. Owen, Medical Tutor at Makerere College, Uganda, to be Medical Superintendent and Principal of the Medical School, Mulago Hospital, Uganda. G. C. Edwards to be M.O., West African Medical Staff.

The annual dinner of the Royal Navy Medical Club will be held on Thursday, April 26th, at the Trocadero Restaurant Piccadilly-circus, London, W. 1. Further particulars can be obtained from the hon. secretary, Surgeon-Commander A. T. Rivers, R.N., Queen Anne's Chambers, London, S.W. 1

EXTENSION OF THE ELIZABETH GARRETT ANDERSON HOSPITAL.—At the annual meeting of this institution it was stated that the new wing is nearing completion and will probably be in use before the end of the year. It is proposed, with the approval of the King's Fund, to provide one or two floors of small paying wards in the building.

VALUATION OF HOSPITALS.—At a conference of Glamorganshire rating authorities it was decided to accept the county valuer's figure for hospitals of £3 per bed; isolation hospitals are to be taken at £2 5s. per bed. Hitherto hospitals have either not been rated at all, or have been assessed on a "sympathetic" basis. It is open to any institution to appeal, and it is now within the power of the local authorities to make a grant in aid.

ABSCESS OF THE BRAIN.

To the Editor of THE LANCET.

SIR,—May I beg the courtesy of your columns to join issue with your leading article of March 10th on this subject, some of the statements in which I feel should not be allowed to pass unchallenged? Your surmise is correct that no one has been able to improve upon Macewen's successes. No one has even been able to approach them. Macewen's *recovery*-rate of 72 per cent. for all cases (18 out of 25) is much the same as the *mortality*-rate for operation cases only in most of the series published of recent years from the large continental clinics,[1] a fact which makes it difficult to find justification for the optimistic tone of the article.

If this depressing mortality-rate is to be lowered earlier diagnosis and treatment of the condition are essential. Success in diagnosis, no less than in treatment, depends on an understanding of the pathology—an understanding not, as your article would have it, of intracranial pathology in general, but of the intracranial pathology of this particular condition, quite a different matter. The intracranial pathology of an abscess differs very definitely from that of a tumour. A tumour is new tissue which displaces the normal cerebral tissue around it, pushing it aside to make room for itself, and this increase in intracranial contents results in a corresponding increase in intracranial pressure. An abscess, on the other hand, increases in size at the expense of the brain substance, which is gradually destroyed by the infecting organism, so that the space previously occupied by cerebral tissue is now occupied by pus, and any increase in the intracranial contents is due mainly to surrounding inflammatory swelling. The degree of this surrounding encephalitis depends upon the virulence of the infection and is only considerable in acute cases, which are the exception rather than the rule. It follows that the increase in intracranial pressure in abscess cases is gradual and slow, and that it is incorrect to state that "a rapid" (and further on "a sudden") "rise of intracranial pressure" is "so characteristic of abscess formation." Nor is it correct to insist upon the "rapid onset of papilloedema," a sign which is generally recognised as being very inconstantly present in abscess cases, or upon "severe headache, drowsiness, and other signs of acute hydrocephalus." Dr. Symonds, in the address referred to in the article, lays stress on this latter point when he says: ". . . . that headache, drowsiness, vomiting and slow pulse are the cardinal signs of brain abscess . . . . is no more true than it is of cerebral tumour."

In the realm of diagnosis the article suggests a doubt of the wisdom of exploration before the appearance of the localising signs. It seeketh after a sign, but often there shall none be given. Of 20 cases which I have had the opportunity of investigating, and upon which my Hunterian lecture was based, 3 out of 12 cases of cerebral abscess, and no less than 4 out of 8 cases of cerebellar abscess showed none of the classical localising signs; they were silent abscesses. Of the former, all three were found by exploration and two recovered; while of the latter, only one was suspected and explored. Again, the localising signs, when they do appear, are late, manifesting themselves only after the latent stage, which lasts on an average four to six weeks, is past—that is to say, when an abscess has been in existence in the brain for that length of

[1] Some recent statistics of mortality-rates (per cent.) are: Beck, from Neumann's Clinic, 1907–1924, 82; Korner, collected statistics, 1925, 65; Nuhsmann, from Halle, 1920–1923, 55; and Lund, from Copenhagen, 1927, 82.

time. Lund[2] says that "Undoubtedly the symptoms mentioned (the various localising signs) are of considerable diagnostic interest, but, as a rule, *they appear relatively late, wherefore the diagnosis ought to be made at some earlier time if possible.*" To insist upon waiting for them is to be as one who would doubt the wisdom of an abdominal exploration for suspected gall-bladder disease until after the appearance of localising signs in the form of attacks of jaundice and gall-stone colic. My whole aim was to attempt to work out a symptomatology of the latent stage in order to provide a basis for the rational presumption of the presence of an abscess, as has been done by the abdominal surgeons in their own special sphere. This presumptive diagnosis would then be confirmed or disproved by exploration. I would say with Lund[2] that "in our struggle for a diagnosis the puncture needle should certainly be our last but also our most important weapon."

Finally as to treatment. We are to "map out" the situation of the abscess "by passage of a brain needle down to—but not through—the resistant wall of the abscess." It sounds delightfully easy, but how often can it be brought off successfully? My experience is that the sense of resistance, if any, is more often than not only sufficient to suggest that one's instrument *may* be impinging upon the abscess, so one pushes it a little further to make sure. Having found the abscess, we are to make "a wide opening in skull and dura," and deliberately to encourage the formation of a cerebral hernia, which is to be "desired." Desired?—when the literature is full of descriptions of operative methods designed to prevent the occurrence of this complication, which, when of any size, leads to a fatal result from purulent meningitis in most cases.

The conclusion of the whole matter is this: that so long as the policy of procrastination in regard to diagnosis and treatment is advocated by those in high places, so long will the mortality-rate of this, at the best, very dangerous condition maintain its present formidable level.

I am, Sir, yours faithfully,

Bath, March 12th, 1928 E. MILES ATKINSON.

THE ASTHMA RESEARCH COUNCIL.

To the Editor of THE LANCET.

SIR,—May I be permitted to add a further suggestion to those made by the Asthma Research Council in your current issue as to possible lines of research. In a recent correspondence in your columns I claimed that my insistence upon a definite use of words like "neurosis" was in order to encourage a more helpful attitude towards neurotic sufferers, and the present occasion adds force to my argument. In your annotation you remark upon the extraordinary varieties of conditions that may give rise to an attack, and add that there is a strong neurotic element in many cases. The medicine of the text-books offers nothing towards the study of this neurotic element, and the proposals of the Asthma Research Council do not refer to it. Yet among those who do not regard this element as something irreducible and inexplicable there is a considerable body of opinion, based upon clinical experience, that asthma is often the physical expression of an emotional state—the equivalent of an anxiety attack. The relation of emotion to the phenomena of sensitisation may perhaps be sought in the curious behaviour of the conditioned reflex, but neither physiologists nor psychopathologists can attack the problem without coöperation. I therefore suggest that the Asthma Research Council should add to their programme the investigation of the psychological aspect of the asthma attack.

I am, Sir, yours faithfully,

London, March 19th, 1928. MILLAIS CULPIN.

[2] Acta Oto-Laryngol., 1927, xi., 479.

STEREO-FLUOROSCOPY.

To the Editor of THE LANCET.

SIR,—My attention has been drawn to the note by Dr. F. H. Humphris in your issue of March 3rd on the latest developments in stereo-fluoroscopic work. It is, I think, only fair to British radiology to point out that Sir James Mackenzie Davidson developed the very same idea, which Dr. Humphris describes, several years before the war. About the year 1908 he asked my late father and Mr. Rocky to design and construct such an apparatus to operate from an ordinary interrupterless transformer unit with a mechanical rectifier. Two gas X ray tubes were fed by this plant, one half cycle of current being passed through one and the other half cycle through the other tube. The tubes thus lit up alternately 50 times per second and were placed side by side at a suitable distance from the patient. The fluorescent screen was observed through a revolving disc which moved in synchronism with the alternating current and contained two slits, so arranged that the eyes of the observer were alternately prevented from seeing the screen. Thus the left eye would only observe the screen when the right tube lit up and the right eye only when the left tube was operating.

The arrangement was a complete success and finally went to America. Obviously, the coming of the small-sized X ray tube and the improved fluorescent screen makes the problem easier, but the idea was conceived and satisfactorily solved in Great Britain approximately 20 years ago.—I am, Sir, yours faithfully,

W. E. SCHALL, B.Sc.

75, New Cavendish-street, W., March 15th, 1928.

To the Editor of THE LANCET.

SIR,—We have read with much interest the account by Dr. Humphris of the so-called "new method" of radioscopic examination by means of stereoscopic attachment. In fairness to British manufacturers, we think it right to point out to you that there is nothing novel about this so-called invention. To the best of our belief, apparatus of this kind was made, in accordance with the suggestions of the late Sir James Mackenzie Davidson, very nearly 25 years ago, and some years afterwards, probably about 1909, the idea was developed and tried out, practically, by the late Sir Archibald Reid. In both of these cases the apparatus in question was constructed by British firms, and much of the design and construction of Sir Archibald's Reid apparatus was carried out by Mr. Fredk. R. Butt, who is still actively engaged in the X ray industry.

Apparently the methods in question did not prove to be of sufficient practical advantage to survive. It may be, of course, that the system now proposed is of a more useful character, but we hope that you will find it possible to give publicity to this letter, as evidence of the priority of British X ray workers in the direction referred to.

We are, Sir, yours faithfully,

X-RAYS LIMITED.

47, Red Lion-street, High Holborn, W.C., March 8th, 1928.

THE POSITION OF THE VOLUNTARY HOSPITALS.

To the Editor of THE LANCET.

SIR,—In your issue of Feb. 25th, Dr. Graham Little fell into error when he deduced the existence of 3000 empty (reserve) poor-law beds from the figures of 19,000 "available" and 16,000 "occupied" beds. It would be just as fallacious to contend that because there are 14,472 available and 12,023 occupied voluntary hospital beds in London (vide King's Fund Report, 1926), therefore there are 2449 empty beds in the voluntary hospitals.

I am, Sir, yours faithfully,

RALPH B. CANNINGS,

March 15th. Secretary, City of London Maternity Hospital

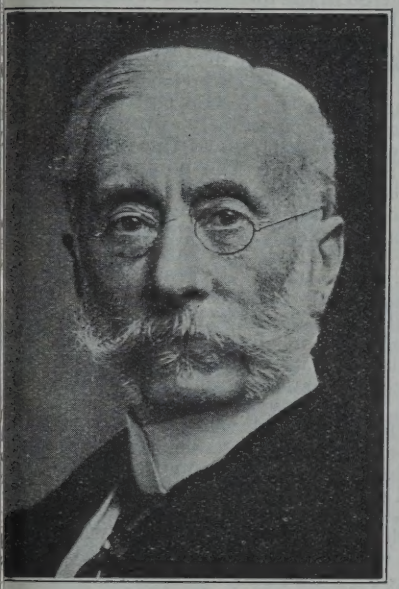
Obituary.

SIR DAVID FERRIER, M.D., D.Sc., F.R.S.,

EMERITUS PROFESSOR OF NEUROPATHOLOGY, KING'S COLLEGE, LONDON.

WE deeply regret to announce the death on Monday last of Sir David Ferrier, the veteran neurologist, whose researches date back from 1870, and whose personal labours by experiment and by writing have contributed, probably more than the work of any one man, to our modern knowledge of the functions of the brain. He died at York House, Kensington, in his eighty-sixth year.

David Ferrier was born on Jan. 13th, 1843, in a suburb of Aberdeen, was educated at the Grammar School of that city, matriculated at the University in 1859, and began his distinguished career as a successful student of the humanities and philosophy; he won the first place in bursary examinations, graduated in arts with first-class honours in both his subjects, and gained also the Ferguson scholarship, the blue riband of young Scottish philosophers.



SIR DAVID FERRIER.

Photograph by Elliott & Fry.

The famous Alexander Bain, psychologist and logician, had been appointed some three years before Ferrier's graduation professor of logic in the University, upon the publication of his works on the Senses and the Intellect and the Emotions and the Will, and to him Ferrier attributed the early direction of his interests, for in 1864 he went to Heidelberg to study psychology, his medical work being commenced there more or less as an after-thought. But in 1865, on return to Scotland, he entered the Medical School of the University of Edinburgh, and three years later graduated in medicine at that University with all possible distinctions. Thomas Laycock, professor of practical medicine in the University, at once appointed him his assistant, and for a time Ferrier worked under Laycock, supplementing his resources by taking pupils. But he soon found the work distasteful—great expositor as he became, coaching for examinations was not his métier—and at this time he made the interesting decision to enter private practice. This experiment did not last long, but none the less it had an influence upon his future. His chief, William Edmund Image, a general practitioner in Bury St. Edmunds, was an unusually accomplished man, a bachelier-ès-lettres, as well as an F.R.C.S., and had not only a large practice in and around the old-fashioned city but a close personal acquaintance with many leaders of his profession in London. He recognised the extraordinary qualities of his assistant, and acquiesced in Ferrier's view that so purely a country environment did not offer the proper outlook, while, as Ferrier would admit when reminiscing, his coöperation in the day's work promised to be of no value to the practice. He himself has said that, with the hearty coöperation of Image, he spent the whole of his time at Bury St. Edmunds in researches in comparative anatomy, and their result was an M.D. thesis on the corpora quadrigemina for which he gained a gold medal in medicine in 1870. In the same year he returned to London at the instance of Prof. Burdon Sanderson, and after holding a post for a short time in the Middlesex Hospital medical school was appointed demonstrator of physiology at King's College, and commenced his famous association with that institution. In 1873 he became lecturer on medical jurisprudence at the hospital, succeeding shortly to the chair vacated by Prof. William Augustus Guy, and was soon appointed assistant physician to the hospital, as well as to the West London Hospital. His association with Prof. Guy is marked by the widely known treatise on forensic medicine, the later editions of which bore their joint names as authors.

From this time forward Ferrier carried on clinical practice while pursuing his investigations into the psychology of the brain. He was a pioneer in hitherto untrodden regions of scientific medicine, and his fame was enhanced by the malignant manner in which he was signalled out by the opponents of research for particular reprobation as a vivisectionist. The results of his studies were given to the world without delay in a series of papers embodying researches into cerebral physiology and pathology, in the Croonian Lectures before the Royal College of Physicians of London in 1874 on the Localisation of Function in the Brain, in further papers on the same subject in the Philosophical Transactions of 1875, and in the Goulstonian Lectures on the Localisation of Cerebral Disease in 1878. But before the delivery of these last lectures he had published in 1876 his important work "The Functions of the Brain," which was recognised at once as a path-making contribution to an obscure and difficult department of physiological and psychological inquiry. The work had its direct outcome from the experimental physiology of Fritsch and Hitzig, who had recognised that in dogs, by exposure of the cerebral hemispheres, and trephining or removing portions of the skull, they were able to call forth certain movements by stimulation of different regions. Ferrier made the whole subject his own, and while many of the facts recorded by him or ascertained by his experiments were tolerably familiar to a small class of observers, the teaching came as a revelation to medical practitioners. The book owed much to Ferrier's early friendship with Hughlings Jackson, for certain of the experimental investigation of brain function was made mainly for the purpose of testing Jackson's theories as to the causes of various forms of epilepsy, while among other sources of inspiration may be mentioned as invitation from Sir James Crichton-Browne, at the time superintendent of the West Riding Lunatic Asylum, to embody in the asylum reports the early results of his experiments. On the publication of this book he was elected F.R.S., and in the following year, the year in which he became assistant physician to the Hospital for Epilepsy and Paralysis, he was elected F.R.C.P. Lond. In 1880 he became physician to the National Hospital for the Paralysed and Epileptic, Queen-square, while at King's College a Professorship of Neuropathology was specially instituted for him.

Ferrier's work is summarised in respect of its clinical value in his clearly written essay on the regional diagnosis of cerebral disease, contributed to Allbutt and Rolleston's System. In this essay a knowledge is assumed of cerebral anatomy, the vascular supply, and the convolutional arrangement of the cortex, while intracranial morbid anatomy is not considered. Attention is focused upon regional diagnosis by considering whether a lesion be essentially irritative or destructive in character, and whether it be such as is calculated to exercise a disturbing influence on regions anatomically remote from the part actually invaded. Within the limits thus laid down by himself, Ferrier tells the story, with full references and documentation, from the time

when our knowledge was confined to a few empirical generalisations, made from the observation of certain forms of aphasia and of unilateral convulsions, up to the knowledge of to-day.

The following appreciations of Sir David Ferrier from Dr. Wilfred Harris and Dr. Kinnier Wilson show well the esteem and admiration which, as philosopher and man, he commanded in the scientific world; they are estimates which would be endorsed by all who had worked with Ferrier or along lines where he had preceded them, and form a noble testimony.

Dr. Wilfred Harris writes: "Ferrier had outlived all of that band of great men, his colleagues at the National Hospital, Queen-square. To the younger generation the names of Hughlings Jackson, Thomas Buzzard, Bastian, Gowers, David Ferrier, and perhaps even Victor Horsley are legendary, and do not naturally evoke the feelings of almost awe and reverence that those who were privileged to work with and for them 30 years ago used to feel for their chiefs. It was Hughlings Jackson's work in the 'sixties on theoretical cerebral localisation, the result of his study of unilateral fits produced by tumours of the brain, that led to the experimental work first by Fritsch and Hitzig in 1870, and shortly afterwards by Ferrier in the laboratories of King's College in the Strand. Hughlings Jackson's was the brain which conceived the theory of the motor functions of a specialised area of the cortex, following on Broca's demonstration of a motor area for speech in the left ascending frontal convolution. Ferrier's training as a physiologist, and his early attraction to the nervous system eminently fitted him as the man to put Jackson's theories to the acid test of practical experimentation on living animals, and though Hitzig had already published some work in this direction, Ferrier's researches were much more fully and methodically planned, using faradic stimulation to the cortex. Endowed with most capable hands and good operating technique, he brilliantly proved Jackson's theories to be right, and settled for all time the groundwork of experimental localisation of brain centres, work which was amplified and confirmed by the later researches of Beevor and Horsley, and more recently by Sherrington and Grunbaum, who had the opportunity of using numbers of anthropoid apes for their experiments. No experimenter worthy of the name escapes making mistakes, to be rectified later by himself or by others, and Ferrier's work in this most difficult field of research was hardly likely to be an exception to this rule. He described the seat of the half-vision centre to be the angular gyrus, as the result of his cauterisation of this centre being followed by hemianopia, and it was reserved for Sharpey-Schafer to demonstrate the now well-known half-vision centre around the calcarine fissure, and that Ferrier's lesions of the angular gyrus had also damaged the subjacent optic radiations. The anti-vivisectors not unnaturally raised a storm over Ferrier's work on dogs, and much ink was slung in the 'seventies and early 'eighties in obloquy of his name, which probably defeated their object by bringing the brilliant young experimenter's name to the notice of the public. Certain it is that for very many years afterwards his name was almost a household word, and his advice as a neurologist was sought far and wide. Though he was for years professor of forensic medicine at King's College, and wrote a work on this subject, it is entirely as a neuropathologist that his name will live. As a clinician he was quick and incisive, and his teachings, brief and clear cut, were perhaps more easily remembered than those of more fluent orators.

"Ferrier's last appearance in the rôle of head of British neurology was in 1913, when he presided at the dinner given to the foreign neurologists present at the International Medical Congress held in London. Though then 70 years of age he was still slim, dapper, and erect as always, and that he retained his interest in neurology for years afterwards was evidenced by his frequent appearance at scientific meetings. Up to the time of his severe illness when attacked by double pneumonia three years ago he still retained remarkable vitality and a comparatively youthful appearance. His death marks a milestone in neurology as the last of the pioneers in this field, but his work must remain as an immemorial monument to a keen brain quick to adapt the theories of the thinker and philosopher to the test of practical trial and experiment."

Dr. S. A. K. Wilson writes: "Sir David Ferrier was the last of the small and choice company of pioneers through whose labours the scientific neurology of to-day has come into being. Nearly 60 years have passed since he commenced researches on the functions of the central nervous system that brought him world-wide distinction, and made his name familiar wherever neurology was taught. With those of Hughlings Jackson, Horsley, and Gowers, it will ever take that honoured position in the memorials of neurological science reserved by common consent for the path-makers and the masters. He was witness of the transition of knowledge of the nervous system and its diseases from the state of empiricism and lucky guesses to its fruition in the fertile soil of accurate neuro-anatomy and experimentally proven neuro-physiology, and was himself one of the protagonists in this amazing revolution. The commonplaces of neural doctrine to-day were the discoveries of his early manhood, and we of a succeeding generation can appreciate but faintly the new world then revealed by the objective methods of precise cerebral experimentation. More than 40 years separate us from the International Congress of 1881, when Ferrier gave a brilliant demonstration of the novelties of cerebral function and localisation before the assembled savants of Europe; and 15 years, too, have elapsed since their successors hailed him at the Congress of 1913, as the doyen of English neurology. If in these later times his work was less often referred to, if the echoes of old controversies had long since died away, if clinicians and surgeons cultivated the neurological field without a thought of the wilderness whose place it took, a moment of quiet consideration would always bring to the mind of those who knew him and worked with or for him an impressive sense of the debt neurology owes to his imagination and to his persistence in following the path of minute and exact experimental research. Only a few of his friends are aware of the personal abuse which this line of investigation brought him, or of the extremes to which his opponents went in their endeavour to discredit his achievement.

"It is on his many services to the experimental physiology of the nervous system that his reputation rests securely, nor can it be diminished by any contention that the technique was comparatively simple and that the material lay ready to his hand and was only waiting to be utilised. Subsequent studies have not altered his conclusions fundamentally even if the growing point of neurology has moved away somewhat from the rather schematic parallel he drew between excitation and response, between structure and function. To many of the younger generation he was known only as a clinician and clinical teacher, and this was possibly not the most original side of the man. A shrewd observer and a keen student of human nature, his contributions to clinical neurology are none the less by comparison not so memorable or so abundant. He had not Jackson's breadth of vision, or Gowers' faculty of patient and painstaking clinical scrutiny; what struck all those whose contact with him was of later period was his mental vigilance and his consuming desire for information. Long after his best years had passed he was still a frequent attendant at meetings of the Neurological Section, the College of Physicians, and the Royal Society, and within a few months of his death was still to be seen on occasion in the library of the Royal Society of Medicine. Nothing was more typical of Ferrier than this hunger for knowledge. On the day of Jackson's funeral in 1911, I walked away with him from the cemetery

and after many minutes of silence, occupied with his own thoughts of his teacher and friend, he suddenly turned and said, 'well, when I cease to take an interest in things it will be time for me to go.' Those of us who were associated with him professionally and otherwise, who experienced his generosity or who knew a little of that side of him that was but seldom revealed, will like to think of Sir David Ferrier as one whose life illustrated in perfection, the meaning of the love of knowledge for its own sake, and who carried undimmed to the end the torch of science put into his hands 60 years before."

The honours which Ferrier received from various seats of learning sufficiently testify to the wide range of his fame. As early as 1878 he became a Lauréat of the Institut de France, while from the Royal Society he received the Marshall Hall prize in 1883, the Baly medal in 1887, and the Royal medal in 1890. The University of Edinburgh made him Cameron Prize-man and awarded him the Moxon medal; he was a D.Sc. of the University of Cambridge, and only last year received the honorary LL.D. from the Univer-sity of Birmingham. At the Royal College of Physi-cians of London he was Harveian orator and Censor. He presided over the Neurological Society in 1894, and over the Medical Society of London in 1913. In connexion with the Neurological Society he was one of the founders and editors of *Brain*, the journal of that society, of whose prominent position he was always frankly proud, and to which he made so many noteworthy contributions.

Few leaders of the medical profession were better known in London to his colleagues than Ferrier; even when he had reached an advanced age his small, upright figure was to be seen regularly at professional gatherings, at social evenings, and in the drawing-room of the Athenæum. Though studiously quiet in voice and demeanour, and never desirous of joining in controversy or in asserting personal views, his conversation with friends was free, intimate, and amusing, for he preserved to the end of his long life an accurate memory, just powers of reflection, and keen appreciation of the ridiculous. Some three years ago he underwent a serious illness—one from which his advisers expected nothing but a fatal issue; but he made so perfect a recovery that his death will come to many as an unexpected event.

He married in 1874 Constance, daughter of Mr. Albert Waterlow, by whom he had one son, Mr. Claude Waterlow Ferrier, the well-known architect, and one daughter.

The funeral service was held yesterday (Thursday) at St. George's, Hanover-square, W.

MAYNARD SMITH, C.B., M.B.LOND., F.R.C.S.ENG.,

SURGEON TO ST. MARY'S HOSPITAL.

WE regret to announce the death of Mr. Maynard Smith, surgeon to St. Mary's Hospital, which occurred on March 18th in the fifty-third year of his age, sadly cut off at the zenith of a valuable life.

Sidney Maynard Smith was born on Sept. 20th, 1875, the son of a civil engineer, who also held an Admiralty appointment at Chatham. He was educated at Epsom College where he distinguished himself as a boy, gaining the entrance scholarship in natural science at St. Mary's Hospital, the institution with which he was closely connected throughout his professional career. He entered the school in 1893, qualified as M.R.C.P. Lond., M.R.C.S. Eng. in 1898, was appointed house surgeon the following year, and later became prosector and assistant demonstrator of anatomy in the medical school. In 1902 he proceeded to the F.R.C.S. and two years later graduated in medicine and surgery in the University of London. He became surgical registrar at St. Mary's Hospital in the same year, and also surgical tutor, and in 1906 was appointed surgeon to out-patients, acquiring shortly charge of the orthopædic department. He was also elected assistant surgeon to the Victoria Hospital for Children. In the meantime he had seen military service in the Boer War, for shortly after the outbreak of hostilities in South Africa he was appointed civil surgeon to the South African Field Force. Here he not only did good work but acquired the material for informing and accurate writing on head injuries and gunshot wounds, while he was decorated for his services. On returning to civil life he became lecturer on practical and operative surgery in the medical school of St. Mary's Hospital. He was also elected assistant surgeon to the London Fever Hospital, so that, with such training and opportunities, it is not surprising that he was now recognised as a leading surgeon, destined to go far in his profession. He contributed a series of articles on military surgery to the "Index of Treatment," and published papers on general surgery in the *Transactions* of the Medical Society, the *Journal of Anatomy and Physiology*, the *British Medical Journal*, and *The Lancet*, establishing his position as a sound clinician and consultant. Military and national duties again supervened.

In 1914 the European War broke out, and Maynard Smith went to France as surgeon-in-chief of the St. John Ambulance Brigade Hospital with the honorary rank of Major. The following testimony to his later work is given in the words of Major-General Sir G. Guise-Moores, who writes as follows:—

"I should like to bear testimony to the loss both the medical profession and the army have sustained by the death of Sidney Maynard Smith. Late in February, 1918, Sir Anthony Bowlby, then the Senior Consulting Surgeon to the British Forces in France, informed me, as D.M.S., Second Army, that we were to have the services of Maynard Smith as consulting surgeon. His skill as a surgeon had preceded him, and was known by his work at the Duchess of Westminster's Hospital at the Base. The Second Army, like many another, had been fortunate in its consultants, both surgical and medical, and it did not take long to make certain that in 'Maynard,' it possessed, besides surgical prowess, a man of sterling qualities of heart and mind. At his own request he was early permitted to pay occasional visits to the front line, to regimental aid posts, and to advance and main dressing stations. He soon acquired a sound judgment in what was essential to efficiency in the care, treatment, and evacuation of wounded. Anything short of this gave his gallant and kindly soul the deepest grief and concern. With any shortcoming he was never content until a remedy was found; and found it invariably was. At the casualty clearing stations where his chief work must necessarily be, his cheery presence was always welcomed, his advice eagerly sought, and his capacity for unobtrusive and arduous work recognised and appreciated, and in the short intervals between the 'crises' of incoming wounded, when alone it was possible to ponder and talk over things past and to come, we found in him a fund of quiet humour, a sense of timely loyalty, a gift of sage counsel, and an entertainment that goes with successful accomplishment."

His medical military career was throughout one of real distinction, as will be gathered from the above testimony and public acknowledgment. He was thrice mentioned in dispatches, gained the Croix de Guerre, and was appointed C.B. in 1918. And again his special experience enabled him to write with authority on many surgical and pathological conditions that had come under his notice in every variety of urgency and extremity. He contributed the section to the official medical history of the war on fractures of the lower extremity, the most valuable of his contributions to scientific literature.

To the smaller circle of his colleagues at St. Mary's Maynard Smith will be more than an ordinary loss, and will ever be remembered as much for his other qualities as for his surgery. He was an invaluable committee man, who never undertook the slightest service without giving of his utmost in energy, time and thought. His fresh outlook and wise judgment have many a time solved a knotty problem of hospital

routine. It did not need the war to prove his great abilities as an administrator, yet here they perhaps showed up at their best. He had a tidy mind which was reflected in all he did. He possessed an exquisite surgical technique, but his fingers were always guided by wise and thoughtful decisions.

Maynard Smith was the victim of a disease which from time to time gave warning that it only slumbered and one day would inevitably have its way. Yet very few even of his friends knew this: fewer still guessed that he knew it. He preserved his secret, and with extraordinary fortitude carried on his busy life, refusing to withhold such services as were constantly demanded of him by a teaching hospital and school. He will always be remembered with affection and admiration.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

INVALIDING FROM THE NAVY.

ON March 15th Lieut-Colonel HEADLAM (Parliamentary Secretary to the Admiralty) dealt with the question of invaliding from the Navy, which was raised on a motion moved by Sir B. Falle last week when the House was "counted out." The previous debate, he thought, had showed that all sides of the House felt that there was something wrong. He could assure the House that the Admiralty were watching this matter very closely, but there was a great deal of misconception, not only in regard to the actual facts which were adduced in the debate, but also in regard to what the results would be if the new suggestion were adopted, and the question of deciding what was attributable and what was not were transferred from the medical authorities at the Admiralty to some outside body. He thought, personally—and he had taken a good deal of trouble in examining the whole system—that hon. Members who took part in the previous debate were unduly pessimistic about the present procedure. He agreed that from the psychological point of view there might be something in the suggestion that the officers and men themselves would be more satisfied if they had some kind of outside Board to which to go, but he would point out that the independent tribunals which they knew so well under the Ministry of Pensions were brought into existence to meet special circumstances arising from the war. It was then obvious that there were hundreds and thousands of cases in which the medical history of men could not possibly be ascertained in the ordinary way. Therefore it was probably quite necessary to set up those special tribunals. But in the case of a service like the Navy, in ordinary times, the medical history of a man was known from the first moment he came on board and his whole history was kept throughout his career, and the doctors before whom he came in the event of his being brought forward for invaliding were men who were perfectly familiar with the kind of service he had had, and were therefore better fitted almost than anyone else to judge whether the illness from which he was suffering was due to the service or not. He would also point out that such a man had on his side, as far as was possible, the doctors, and was given every chance of stating his case and of calling witnesses if necessary.

Mr. GROVES: I dispute that statement.

Procedure of the Board of Survey.

Colonel HEADLAM said he would tell the House exactly what the Board of Survey did. When an officer or rating in hospital or serving in a ship or establishment was considered to be unfit for further service he was brought forward for survey with a view to invaliding. Medical Boards of Survey were held twice in each month under the authority of the Commander-in-Chief or Senior Officer present. The Board consisted of the medical officer in charge of the hospital, who acted as president, and three medical officers, two of whom were senior medical officers of the hospitals and one a senior medical officer of the Fleet or depôt. It had been suggested that there should be an executive officer on the Survey Board. That matter had been very carefully considered by the Admiralty, and the general opinion was that nothing would be gained by reverting to a practice which was abandoned in 1914. The questions to be decided were of a purely medical nature and the presence of an executive officer would not strengthen the tribunal. He would either interfere with the medical officers in the performance of their duties or would be a mere figure-head and wasting his time.

Lieut.-Commander KENWORTHY: Could he not decide if the doctors disagreed?

Colonel HEADLAM said that if the hon. and gallant Member would wait he would see that that was provided for. The medical officer who brought the case forward appeared before the Board in order that the surveying officers might receive the fullest information concerning the case. A complete history of each case was made out, showing the details of the onset, course, and final state of the disability for which the patient was being surveyed. Prior to survey each officer or rating was given a form to fill in, on which he was requested to state what in his opinion was the cause of his disability. The Board of Survey was required to investigate and record an opinion whether the disability was attributable to, or aggravated by, service (pre-war, war, or post-war), and if not, to what specific condition it was attributed. Those reports of the Board of Survey, with a statement by the officer or man concerned, were sent to the Commander-in-Chief, who was an executive officer and who came to a decision with all the facts before him.

Dr. VERNON DAVIES: Are we to understand that the Medical Survey Board simply decide the case from the history sheets of the man, and however difficult the diagnosis may be, they form their opinion as to attributability or not purely on the record of the man's medical history?

Colonel HEADLAM said that the Board saw the man's statement and the man could put forward such evidence as he liked. After the decision of the Commander-in-Chief the case was sent to the Admiralty. Every case was carefully scrutinised and investigated by the medical authorities at the Admiralty, who examined all the records bearing on the case.

Mr. MACKINDER: It is done purely on the history of a man's case and not by personal examination.

Colonel HEADLAM: They have all the papers before them.

Lieut.-Commander KENWORTHY: Everything except the patient.

Medical Consultative Board and Hygienic Conditions.

Colonel HEADLAM said that he wished the House to understand that if there was any bias in a case of this kind, the bias was on the side of the man as far as the judges were concerned. In general, he would say that there was very little justification for the attacks that were made against the existing system. It might be perfectly fair to say that the rules by which these matters were judged were too severe and that the doctors were not given sufficient latitude, but to blame the existing authorities was not fair, and the charge that the Board of Admiralty was not the proper judge in the final resort in these cases had, he thought, not been substantiated. It was the rules that were of importance and not the tribunal. This, however, was a matter which the Admiralty agreed required the most careful attention. They were looking into it from every aspect. Not only was there a Joint Committee sitting now, and examining the question of attributability in all its aspects, but they had referred the whole question as regarded hygienic conditions in the Navy to a special Medical Consultative Board of outside specialists and they were awaiting the reply from those specialists to guide them to a certain extent in the policy that they should pursue. They felt that the present system as regarded invaliding and the adjudication of attributability or otherwise was a fair one, but they wanted to be perfectly sure. They realised that the health of the Navy was of primary importance. It was, however, very easy to exaggerate the facts about tuberculosis in the Navy. The truth was that the incidence of the disease seemed to be rather less in the Navy than in civil life. They knew more about it in the Navy because the conditions of inspection were such that they found out the cases very early, whereas in civilian life they might escape observation for a considerable period of time. He could assure the House that they were fully alive to the situation.

The motion was agreed to.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 14TH.

Infant Mortality and Under-nourishment.

Major ROPPER asked the Minister of Health whether he had now received the reports of the medical officers of health for Houghton-le-Spring and Chester-le-Street; and whether they showed that there had been any increase in the infant mortality-rate due to want of proper food and nourishment of mothers and children.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend has received reports from the medical officers of health of the districts mentioned. The infant mortality figures for these districts during 1927 have just reached me and show a small increase in each district as compared with 1926, though the rates were lower than

for the years 1924 and 1925. Only the report of the M.O.H. for Houghton-le-Spring suggested under-nourishment as one of the causes of the increase, and his report was not written until Feb. 22nd. My right hon. friend is advised that other medical authorities in Durham attribute the temporary increase in infant mortality in that county during the last few months of 1927 to the exceptional prevalence of bronchitis and pneumonia.

Maternal Mortality.

Sir ROBERT THOMAS asked the Minister of Health whether, in view of the lack of improvement in the maternal mortality-rate, he would, with a view to creating a more efficient maternity service, consider the advisability of modifying the present maternity benefit in such a way as to provide medical and nursing services in addition to a cash payment, and of linking up such services with maternity and child welfare work of local authorities.—Sir KINGSLEY WOOD replied: The question of the advisability of modifying the present arrangements for maternity benefit under the National Health Insurance Scheme in the direction indicated by the hon. Member was raised at a recent meeting of the Approved Societies Consultative Council and was referred by them to a special Subcommittee. As soon as my right hon. friend receives the report of the Council on the subject, it will have his most careful consideration.

Mr. GREENWOOD asked the Minister of Health whether he had been informed of a resolution passed on Feb. 28th, at a meeting of 600 representatives of local authorities and voluntary societies in touch with the problem of maternal mortality, at which attention was called to the urgent need for medical inquiry into all deaths due to childbirth, further training and experience in midwifery as a preliminary to general practice in medicine, the appointment of an official committee to advise upon the whole question of the training and employment of midwives, action to induce local authorities to make their maternity services adequate, the readjustment and extension of national health insurance so that medical and midwifery services should be available for mothers, both for antenatal care and during and after confinement; and whether, in view of the fact that 3000 mothers died in childbirth annually, and many were injured, he could see his way to taking immediate action on the lines suggested by the conference.—Mr. CHAMBERLAIN replied: The answer to the first part of the question is in the affirmative. As regards the second part, I had already had these matters under consideration in connexion with the recent report issued by my Department on the "Protection of Motherhood," and I am taking the necessary action to give effect to the recommendations contained in that report on the first four points mentioned in the question. As regards the health insurance point, I would refer the hon. Member to the answer given yesterday on this subject to the hon. Member for Anglesey.

New Method of Paying Pensions.

Captain FRASER asked the Minister of Pensions whether he had in contemplation any changes in the method of paying war pensions; what those changes were and when they would be introduced; what classes of pensioners would be affected; what objects he hoped to achieve by the changes; and whether the ex-service man's associations had been consulted.—Major TRYON replied: An important change in the method of payment of war pensions will come into operation next week. The pensioners affected will be all those whose pensions are paid weekly through the Post Office—namely, those of disabled men, their widows and dependants. The central feature of the new system of payment will be the discontinuance of identity certificates, or ring papers. These documents will be surrendered to the Postmaster for cancellation and withdrawal, and the pensioner will receive instead a book of orders, on presentation of which payment will henceforth be made each week at the appropriate Post Office. The new system will be essentially the same as that already in use for old-age pensions and for widows' contributory pensions. It is estimated that a substantial reduction in administrative costs will be secured by the extension of this system to war pensions, but, while the object in view has been uniformity and economy in administration, I am satisfied that pensioners will find the new arrangements simple and convenient. The ex-Service representatives on the Standing Joint Committee and a representative of St. Dunstan's have been consulted on this aspect of the matter and have expressed their approval of the change. No change is at present contemplated in the arrangements for paying the pensions of officers or nurses, or of officers' widows or dependants.

Drunkenness in London.

Mr. BRIANT asked the Home Secretary the number of proceedings for drunkenness and convictions for drunkenness, male and female, in the Metropolitan police district and the City of London for the calendar years 1918 to 1927 inclusive.—Sir WILLIAM JOYNSON-HICKS replied: All available figures in this connexion are published annually in the Volumes of Licensing Statistics, the latest of which is for the year 1926. As regards the year 1927, the figures are not yet completely compiled, but I can give provisional figures as follows: In the Metropolitan Police District the total number of proceedings was 30,123, leading to 21,177 convictions of males and 5977 of females, and in the City of London the figures were 411,293 and 84 respectively. The following is a statement of proceedings and convictions for drunkenness in the Metropolitan Police District and City of London during the years 1918 to 1926:—

Year.	Metropolitan Police District.*				City of London.			
	Proceedings.	Convictions.			Proceedings.	Convictions.		
		M.	F.	Total.		M.	F.	Total
1918 ..	11,358	6690	3211	9901	294	194	44	238
1919 ..	23,683	15,486	5188	20,674	446	322	57	379
1920 ..	33,185	23,581	6375	29,956	491	399	44	443
1921 ..	30,091	21,916	5494	27,410	416	329	49	378
1922 ..	33,912	24,389	6410	30,799	557	432	102	534
1923 ..	32,983	23,414	6610	30,024	498	396	70	466
1924 ..	33,018	23,512	6536	30,048	426	332	57	389
1925 ..	32,900	23,197	6384	29,581	442	334	60	394
1926 ..	32,010	22,631	6226	28,857	388	269	48	317

* This district consists of the Counties of London and Middlesex, and parts of the Counties of Essex, Hertford, Surrey and Kent, including the County Boroughs of East Ham, West Ham, and Croydon. M. = Male; F. = Female.

Health Conditions in Artificial Silk Factories.

Mr. KELLY asked the Home Secretary whether the Home Office had received any reports as to the conditions of health of workpeople employed in artificial silk factories; and, if so, would he make known to the House his decision on these reports.—Sir WILLIAM JOYNSON-HICKS replied: I have received reports by the Medical and other Inspectors of Factories who have been visiting these works. It appears from these reports that the conditions generally are satisfactory, but cases of conjunctivitis have occurred at one or two works, and there have also been some cases of dermatitis. Suitable precautions are being taken in each case and the hon. Member may be assured that the conditions will continue to receive the special attention of the Medical Staff.

Notification of Diphtheria.

Dr. VERNON DAVIES asked the Minister of Health if he would issue a circular to all local authorities, pointing out that, in view of the difficulty of diagnosing diphtheria and the desirability of immediate treatment, it was advisable for medical practitioners to notify suspicious cases without waiting for the results of the bacteriological examination, even though, as a consequence of this practice, a percentage of cases eventually proved to be non-diphtheritic.—Mr. CHAMBERLAIN replied: The difficulty in giving effect to the suggestion of my hon. friend is that the obligation on medical practitioners under the Infectious Disease (Notification) Acts is to notify patients actually suffering from infectious diseases. I could not accordingly issue such a circular as he suggests without an alteration of the law.

Approved Societies and Additional Benefits.

Mr. RHYS DAVIES asked the Minister of Health how many approved societies had been compelled to abandon their schemes of additional benefits through lack of funds, temporarily or otherwise, since the results of the last valuation were declared; and the approximate number of insured persons covered by those societies.—Mr. CHAMBERLAIN replied: No approved society has been compelled through lack of funds to abandon its whole scheme of additional benefits, but about 100 societies (covering a total membership of between three and four million insured persons) which have included dental and ophthalmic benefits in their schemes, have found that the demand for those benefits amongst their members has so far exceeded the expectation that the amounts allocated to the benefits for a particular year have been exhausted before the end of the year, and they have consequently been obliged to defer the authorisation of claims until the beginning of the following year, when further money became available. In nearly every case the authorisation of claims for the benefits has now been resumed.

Surplus Milk and Necessitous Areas.

Mr. BENJAMIN SMITH asked the Minister of Health whether his attention had been called to the considerable surplus of milk produced annually in excess of the quantity retailed for human consumption; and whether he would consider the question of organising arrangements for supplies

to be placed at the disposal of medical officers of health in necessitous areas for distribution to children and sick persons.—Mr. CHAMBERLAIN replied: I understand that the facts are as stated in the first part of the question. As regards the second part, local authorities are empowered to supply milk for expectant and nursing mothers and young children who are medically certified to need a supply on grounds of health.

Pregnant Women and Sickness Benefit.

Dr. VERNON DAVIES asked the Minister of Health if he was aware that many employers refused to allow insured women employees to remain at work during the late months of pregnancy; and if under these conditions such women were granted sickness benefit under the National Health Insurance Regulations.—Mr. CHAMBERLAIN replied: I am aware that some employers do not allow their women employees to remain at work when in an advanced stage of pregnancy. Any such rule of her employer does not in itself entitle an insured woman to sickness benefit under the National Health Insurance Act, but if she can produce medical evidence, to the satisfaction of her approved society, that she is incapable of work, she would be entitled to benefit.

National Health Insurance Dental Treatment.

Mr. HURST asked the Minister of Health whether persons insured under the National Health Insurance Act were to be deprived of their free choice of dental attendant, of the advantages of private treatment, and to be given institutional treatment at clinics in lieu thereof? Mr. EDMUND WOOD asked the Minister of Health whether it was his intention to set up dental clinics under the National Health Insurance Bill; and, if so, whether this would in any way affect the right of the insured contributor to choose his own dental attendant.—Mr. CHAMBERLAIN replied: Approved societies are not at present empowered to establish dental clinics for the provision of dental treatment for their members, but some societies are of opinion that in large industrial centres the setting up of dental clinics might be attended with some advantages. The question has been very fully considered by the Dental Benefit Joint Committee, which is composed equally of representatives of the dental profession and of approved societies of all types, and that Committee has recommended that in order to test the desirability of this form of treatment, one or more experimental clinics should be set up. Under the National Health Insurance Bill now before the House, provision has accordingly been included which would enable this to be done, subject to regulations which would have to be laid before Parliament. There is, however, no intention of making it compulsory upon any insured person to obtain his treatment in a clinic if he would prefer to be treated by a private practitioner, and I am satisfied that freedom of choice of dentist must be retained as a cardinal principle in any arrangements that may be made.

Welfare of Blind Persons.

Captain FRASER asked the Minister of Health if he would adopt the recommendations, on pages 17 and 18 of the seventh Report of the advisory committee on the welfare of the blind, that a detailed inquiry should be made into the financial and other circumstances of the 31,667 so-called unemployable blind persons in England and Wales.—Mr. CHAMBERLAIN replied: Yes, Sir, I propose to ask the local authorities concerned to furnish me with the return suggested by the Advisory Committee.

FRIDAY, MARCH 16TH.

Diphtheria Epidemic at Whittlesey.

Mr. DAY asked the Minister of Health the number of deaths that had occurred through the diphtheria epidemic at Whittlesey, in Cambridgeshire.—Mr. CHAMBERLAIN replied: Since the beginning of this year three deaths from diphtheria have been registered in the Urban District of Whittlesey.

MONDAY, MARCH 19TH.

Infantile Mortality in the Colonies.

Sir JOHN POWER asked the Secretary of State for the Colonies whether in recent years there had been any general decrease in the infantile mortality in the colonies, protectorates, and mandated territories in Africa; and whether any special efforts were being made to deal with the problem of infant mortality in other countries.—Mr. AMERY replied: It is exceedingly difficult as yet to obtain reliable returns of births and deaths among the populations of tropical Africa, but in areas from which the returns may be regarded as fairly accurate, as in the Buganda kingdom of the Uganda Protectorate, and in certain West African towns, there is evidence of slow improvement in the infant mortality-rate. In most areas, however, the rate remains regrettably high. The Governments of tropical Colonies are fully alive to the importance of this matter. Infant welfare clinics are being established and women doctors, nurses, and health visitors appointed for special duty; the work of these officers, notably in Malaya, the Gold Coast, and Sierra Leone, has been of a high order. In this connexion I would specially mention the work of voluntary agencies, such as the Child Welfare League of Kenya and the Child Welfare Society in Singapore, and the efforts which have been made in the West Indian Colonies to deal with this problem.

Employment of Women in Indian Mines.

Lieut.-Commander KENWORTHY asked the Under Secretary of State for India how many women, approximately, are employed underground in the Indian mines.—Earl WINTERTON replied: The average number so employed daily in 1926 was 31,889. The Government of India are considering making regulations to prohibit the employment of women underground by progressive stages in certain classes of mine (including the chief coal mines) and forthwith in others.

Disabilities of Naval Recruits.

Replying to Mr. HORE-BELISHA, Lieut.-Colonel HEADLAM (Parliamentary Secretary to the Admiralty) said: The disabilities for which recruits to the Royal Navy and Royal Marines were discharged within 12 months of their engagement during the years 1926 and 1927, are shown in the following list:—

Disease or injury.	*1926.*	*1927.*
Diseases caused by infection:—		
Pneumococcal infection (lungs)	4	1
Rheumatic fever	6	8
Tuberculosis (pulmonary)	11	7
Tuberculosis (non-pulmonary)	3	5
Other diseases caused by infection	3	3
Nervous and mental diseases:—		
Diseases of spinal cord	1	1
Paralysis	—	1
Epilepsy	9	5
Neurasthenia	3	4
Other nervous diseases	11	15
Insanity	2	4
Diseases of the eye	34	24
Diseases of the ear	66	66
Diseases of the nose	—	2
Diseases of circulatory system:—		
Diseases of the heart (organic)	29	32
Diseases of the heart (functional)	2	6
Diseases of the arteries	1	1
Diseases of the blood and spleen	1	—
Diseases of the lymphatic system:—		
Other diseases	—	1
Diseases of glands and internal secretion	4	[illegible]
Diseases of the respiratory system:		
Bronchitis	—	[illegible]
Asthma	2	[illegible]
Fibrosis of lung	3	[illegible]
Pleurisy	3	[illegible]
Other diseases	1	—
Diseases of the digestive system:—		
Diseases of teeth and gums	2	[illegible]
Mouth, palate, fauces, pharynx	1	—

Smoke Abatement.

Mr. NAYLOR asked the Minister of Health whether h could give particulars showing to what extent count councils and sanitary authorities in England and Wal had availed themselves of the powers given them under th Public Health (Smoke Abatement) Act to take proceedin and to pass by-laws respecting smoke abatement.—S KINGSLEY WOOD replied: By-laws respecting the emissio of smoke have been made by 14 local authorities and co firmed. I have no particulars as to the extent to which loc authorities generally have taken proceedings, but a goo deal of useful work is being done.

Mr. NAYLOR asked the Minister of Health whether, as th result of his circular to county councils and sanitary auth rities, drawing their attention to the Public Health (Smok

Abatement) Act, 1926, any regional committees, with either executive or advisory functions, had been formed.—Sir KINGSLEY WOOD replied: Two regional advisory committees and one executive committee have been set up since the issue of the circular, in addition to two advisory committees previously appointed. A committee has also been appointed by a conference of representatives of local authorities to report on questions of smoke abatement in the Greater London area.

Medical News.

UNIVERSITY OF DUBLIN, SCHOOL OF PHYSIC, TRINITY COLLEGE.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.—PART I.

Materia Medica and Therapeutics; Medical Jurisprudence and Hygiene; Pathology and Bacteriology.—*A. G. Thompson, *Lilla M. Spiller, T. B. M'Mahon, C. M. Taylor, M. E. Kirwan, R. P. M'Garrigle, E. B. A. Solomons, and J. E. R. Keyms.

PART II.

Medicine.—*F. G. Stewart, *D. S. P. Wilson, H. S. Smithwick, Marie M. E. Lea-Wilson, F. O. W. A. Mahon-Daly, G. W. F. Pratt, William Crawford, H. E. Knott, E. S. Adderley, Hyman Dundon, A. G. C. Ffolliott, A. A. Morgan, H. R. F. Tweedy, E. du Plessis Meiring, H. J. Robinson, R. F. W. K. Allen, A. J. Burden, C. R. Harris, G. Q. Chance, and L. R. H. Keatinge.

Surgery.—*F. G. Stewart, J. E. Wells, Julius Sayers, A. G. C. Ffolliott, Kenneth Watson, D. M'M. Carson, E. K. Malone, A. C. C. Charles, J. R. Hanna, Christina M'Donald, William Crawford, Wilfreda D. C. T. Pigott, H. E. Knott, L. R. Brumberg, A. A. Morgan, C. R. Harris, and C. M. O'Brien.

Midwifery.—*C. P. Martin, *F. R. Falkiner, *I.W. Pigott, Cecil King, J. T. M'Ginn, R. M. Wilson, J. F. K. MacCarthy-Morrogh, J. E. M'Mahon, A. R. Ewart, H. S. North, R. H. Bland, Mollie Finegan, C. E. G. Nunns, J. A. Dowds, and A. J. Burden.

* Passed on high marks.

RUSSIAN CONGRESS OF RADIOLOGY.—The fifth Congress of Radiology of the U.S.S.R. will be held at Kiev from May 19th to 23rd. Among the subjects of discussion will be (1) changes in cells under the influence of rays; (2) the classification and radiodiagnosis of diseases of the joints; (3) the functional and anatomical changes in the gastro-intestinal canal after operation; and (4) the radio-therapy of diseases of the blood-forming system. Those wishing to read papers should send a résumé of the proposed communication to the Secretary before April 15th. The medical men in charge of the arrangements are anxious to see their foreign colleagues at the Congress, and will procure the necessary permits for arrival and departure, besides providing for comfortable quarters at Kiev. Correspondence should be addressed to the Secretary, Dr. B. M. Berenstein, Kiev (U.S.S.R.) Roentgen Institut, 7, Leon Tolstoi-street.

MEDICAL SOCIETY OF LONDON.—The 155th anniversary dinner, held at the Trocadero Restaurant, under the chairmanship of its President, Mr. Herbert W. Carson, was attended by about 135 guests and members. Lord Carson, proposing the toast of the Society, testified to the growing understanding and goodwill between the legal and the medical professions, who coöperated in many ways. One vital question, however, on which they would soon have to get together was the legal definition of insanity. The legal profession, after doing their best, had been able to come to no better conclusion than that the lunatic was a person of unsound mind; that was the only definition that Parliament had been able to give, and that was the legal definition to-day. Lord Carson had found doctors at their worst in the witness-box; he often felt inclined, he said, to invite the medical men who appeared for one or other side to walk over to his chambers for a private conference, when he felt sure they would leave agreed. The President, in his reply, said that the Society had admitted 100 new Fellows in 1927. The lease on their present premises expired in 14 years, and they would then be faced with the expense of finding new premises. For the last 100 years, he said, the manuscript of John Ward's diary had been lying in the Society's safe. This was not a medical work, but a commonplace book, written by a vicar of Stratford-on-Avon some 40 years after Shakespeare's death and containing many references to the social life of London and Stratford-on-Avon at the time of the poet. It would be put up for auction at Sotheby's in April, when he hoped the manuscript would not leave the country. The toast of "The Visitors" was proposed by Sir John Rose Bradford, and responded to by Surgeon Vice-Admiral Haskell and Dr. F. G. Crookshank.

UNIVERSITY OF OXFORD: *University College.*—Mr. Pat. C. Mallam, B.M., of Queen's College, has been elected to a Radcliffe Travelling Fellowship of £300 a year. It is tenable for two years, during 15 months of which the holder must engage in foreign travel and study. Dr. Mallam was formerly President of the Oxford University Boat Club, and was subsequently a student and resident at St. Mary's Hospital.

UNIVERSITY OF ABERDEEN.—The Senatus has resolved to confer the degree of LL.D. on Dr. J. A. MacWilliam, F.R.S., Emeritus Professor of Physiology of the University.

LONDON VEGETARIAN SOCIETY.—The First Arnold Hills Memorial Lecture will be delivered by Dr. B. P. Allinson, the President, in the hall of the Royal Society of Arts, John-street, Adelphi, W.C. 2, on Monday, March 26th, at 8 P.M. His subject will be Vegetarianism and Modern Medical Science, and admission will be free.

CONGRESS OF THALASSOTHERAPY.—As already announced, the fifth International Congress of Thalassotherapy will be held at Bucharest and Constanza from May 21st to 29th. The Roumanian authorities have placed at the disposal of the Privy Council a limited number of invitations to, and programmes of, the Congress, and these will be sent to any duly accredited delegate on application to the Council.

MELBOURNE HOSPITALS.—To avoid overcrowding of the Melbourne hospitals the Government of Victoria is about to provide 460 additional beds and to establish a clinical hospital in connexion with the Melbourne University. The latest statistics show that the present accommodation of the Melbourne hospitals is between 1300 and 1400. The cost of the additions will be £460,000, to which the public will be asked to contribute. The Children's Hospital at Melbourne is also extending, an orthopædic section being in course of erection at Frankston, 26 miles from the town. This hospital will have accommodation for 100 patients, and is to include 12 beds for isolation and observation cases.

IRISH MEDICAL SCHOOLS AND GRADUATES ASSOCIATION.—The jubilee banquet of this Association was held on St. Patrick's Day, Saturday, March 17th, at the Savoy Hotel, London, Mr. G. W. Dawson, F.R.C.S.I., presiding, when the principal guest was General Sir Hubert de la Poer Gough. After the loyal toasts, the President carried out the interesting ceremony of presenting the Arnott memorial medal to Lieut.-Colonel W. P. MacArthur. Mr. Dawson, in introducing Colonel MacArthur to the audience, said that the Arnott medal was given in recognition of signal service to the world by a medical man, and he knew that he need not dwell upon the claims to the award of the professor of tropical medicine in the Royal Army Medical College. Colonel MacArthur was well known alike as a scientific worker, where his studies in parasitology had been especially valuable, and as a medical historian. Colonel MacArthur, who stated, amidst cheers, protests and laughter, that he came from the "black north," firmly supported his country as a national entity, though he admitted that when he had attempted to talk Irish in Ireland no one understood him—he was considered to be speaking Chinese. A second presentation followed of an illuminated address to Dr. William Douglas, who was an original councillor of the Association, having served on that body for 50 years. Colonel G. Moore, M.D., past chairman of the council, introduced Dr. Douglas as a veteran friend, and Dr. Douglas, in thanking the Association for the honour done to him, owned also to being from the "black north," while he sketched in a few words the development of Belfast from the days when he first remembered it until now. The toast of "The Guests" was proposed by Wing-Commander William Tyrrell, who wished that the company had chosen a better vehicle than himself for informing the company of the merits of Sir Hubert Gough, their principal guest, and of Mrs. Claude Beddington, whom he also associated with the toast as a well-known Irish woman, a patron of the art of music. The Gough family, said Wing-Commander Tyrrell, was a famous one in Ireland, and the value of their military services to the Empire had been marked by two V.C.'s and much campaigning. Their guest, himself the son of one of those V.C.'s, possessed numerous military distinctions and decorations, earned in India, South Africa, and the late war, when he commanded the Fifth Army. Sir Hubert Gough, in a brief reply, said that he was obeying an indication from the Chairman that politics were to be eschewed, while, for his own part, he regarded Ireland as one country and the British Empire as the brightest jewel in the Irish Crown. Mrs. Beddington's reply took the form of a series of Irish stories admirably told. The closing toast of "Prosperity to the Association," coupled with the name of the President, was proposed by Dr. Bertram Watson. The speaking was interspersed with songs by Miss Mary Sheridan, Mr. Patrick Hughes, and Wing-Commander Tyrrell.

NATIONAL UNIVERSITY OF IRELAND: *University College, Cork.*—Dr. E. V. Cantillon has been appointed lecturer in materia medica, and Dr. T. Donovan lecturer in therapeutics. It is understood that the Chair of Materia Medica and Therapeutics will not be filled.

UNIVERSITY COLLEGE HOSPITAL.—The Duke of Bedford, who is retiring from the office of president, which he has held for 30 years, appeals for £30,000 to clear off the accumulated debt before he is succeeded by Prince George, the new president. During the Duke's term of office the hospital has increased from 200 to 525 beds.

HOSPITAL EDUCATIONAL LECTURES.—King Edward's Fund reports that over 50 institutions have taken advantage of the educational lectures for schools and colleges upon hospital work. The scheme has been an undoubted success, and the London County Council has given permission for children from the central schools to attend the lectures, and will add to its general catalogue of slides duplicates of those used in the lectures.

MENTAL AFTER-CARE ASSOCIATION.—The annual meeting of this association will be held on Thursday, March 29th, at 3 P.M., at the Clothworkers' Hall, Mincing-lane, London, E.C. Sir Charles Wakefield, the President, will take the chair, and the speakers will include Lord Sandhurst, the Lord Chancellor's Visitor in Lunacy, Sir Frederick Willis, chairman of the Board of Control, and Mrs. Dunn Gardner, chairman of the L.C.C. Mental Hospitals Committee.

DIPLOMA IN PUBLIC HEALTH.—A three months' course of lectures and demonstrations on clinical practice and in hospital administration has been arranged by the Metropolitan Asylums Board. It will be given by Dr. F. H. Thomson at the North-Eastern Hospital, St. Ann's-road, Tottenham, N. 15, on Mondays and Wednesdays at 4.45 P.M., and alternate Saturdays at 11 A.M., beginning on Wednesday, April 11th. Particulars may be had from the Clerk to the Board, Victoria Embankment, London, E.C. 4.

KING GEORGE'S HOSPITAL.—Owing to an extension of the radius of the operations of King Edward's Hospital Fund for London, the London County Council have found it possible to devise a scheme for a hospital to serve the Thames-side area, which contains the Becontree Estate. With the support of the Fund, and the concurrence of the Ministry of Health, a new voluntary general hospital, containing from 300 to 400 beds, will be erected at Becontree. A letter has been received from the Home Secretary stating that the King has approved of the new hospital being known as "King George's Hospital."

TUNBRIDGE WELLS HOSPITALS.—This is the centenary year of the Tunbridge Wells and Counties General Hospital at Tunbridge Wells, and it is to be marked by the commencement of the erection of a hospital of 150 beds and to include a special wing to amalgamate the local Eye and Ear Hospital. The cost approximately will be £80,000, but of this figure a large sum will accrue from the sale of the General Hospital.

HOSPITAL SAVING ASSOCIATION.—This association has published figures showing the increased importance of direct contributions from patients to the funds of voluntary hospitals on the lines recommended by Lord Cave's Committee. For July, 1924, the membership of the association was 62,390, and in July, 1927, the number had increased to 351,865. The total membership is now over 400,000. In July, 1924, the sum distributed to hospitals was £14,032, while for 1927 it reached £153,670. These sums were paid to hospitals as special contributions in respect of the cost of the treatment of members of the association or of their dependants.

MEDICAL WOMEN'S INTERNATIONAL ASSOCIATION.—A meeting of this Association will be held at Bologna on Wednesday, April 11th, and will be followed on April 12th, 13th, and 14th by an open meeting, to which all women doctors are invited. The subjects for discussion will be (1) medical measures for the protection of children and young persons in the various countries, (2) diseases of the eye in relation to general medicine. A large attendance is expected from the 22 countries which are at present affiliated to the association, as well as from other countries which are hoping to form organisations. The Italian railway authorities have granted special facilities, and various entertainments have been arranged, including a reception by the municipality and a dinner at the local Fascist headquarters. The Italian Association of Women Doctors is holding its annual meeting during the same week, and wishes to convey to the medical women of all countries a message of welcome to Bologna. Further particulars may be had from the hon. secretary of the association, Miss Martindale, M.D., 28, Weymouth-street, London, W. 1.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY, March 26th.—8 P.M., ODONTOLOGY, ELECTRO-THERAPEUTICS. Special discussion on the Pulpless Tooth. Speakers for the Section of Odontology, Mr. Frank Coleman (opener), Mr. Owen C. Morphy, Mr. A. T. Pitts, Dr. A. Livingston, Mr. St. J. Steadman, Mr. B. Mendleson, and Mr. A. F. MacCallan; for the Section of Electro-Therapeutics, Dr. H. M. Worth (opener), Dr. G. Murray Levick, Dr. Meyrick Jones, Dr. J. F. Brailsford, Mr. Norman Grellier, Dr. A. C. Jordan, and Dr. B. G. Batten.

TUESDAY.—5 P.M., MEDICINE. Papers: Dr. F. Parkes Weber: A Note of Idiosyncrasies and Abnormalities in Human Beings. Prof. D. W. Carmalt-Jones: New Zealand View on Goitre.

WEDNESDAY.—5 P.M., COMPARATIVE MEDICINE. Short Papers: T. Dalling, J. H. Mason, and W. S. Gordon: (1) Intradermic Tuberculin Testing in Cattle; (2) Transference of Maternal Immunity in Sheep. J. W. Trevan: The Present State of Knowledge of Sex Hormones. H. J. Parish: B.C.G. Experiments in Guinea-pigs. C. C. Okell: Diphtheria Infections and Diphtheria Immunity in Horses.

THURSDAY.—8.15 P.M., PSYCHIATRY. Members of the Medical Section of the British Psychological Society have been invited to attend this meeting. Discussion on the Ætiology of Alcoholism. Openers: Dr. Bernard Hart and Dr. Edward Mapother (for the Section of Psychiatry); Dr. Edward Glover and Dr. Crichton Miller (for the British Psychological Society).

MEDICAL SOCIETY OF LONDON, 11 Chandos-street, Cavendish-square, W.

MONDAY, March 26th.—8.30 P.M. Advances in the Treatment of Cancer of the Cervix Uteri. Discussion to be introduced by Dr. Herbert Spencer and Dr. Max Cheval, of Brussels.

MEDICAL SOCIETY FOR THE STUDY OF VENEREAL DISEASES, 11, Chandos-street, Cavendish-square, W.

FRIDAY, March 30th.—8.30 P.M., Mr. Eardley Holland and Dr. F. H. Lacey: The Antenatal Treatment of Venereal Disease—Gonorrhœa (second meeting). A discussion will follow.

ST. JOHN'S HOSPITAL DERMATOLOGICAL SOCIETY.

WEDNESDAY, March 28th.—4.15 P.M. (at St. John's Hospital, 49, Leicester-square), Clinical cases. Dr. R. Craik: Monilia.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS, Pall Mall East, S.W.

TUESDAY, March 27th.—5 P.M., Dr. J. S. Collier: Epilepsy. (Lumleian Lecture (2).)

THURSDAY.—5 P.M. (Lumleian Lecture (3)).

ROYAL INSTITUTION, Albemarle-street, W.

THURSDAY, March 29th.—5.15 P.M., Group-Captain Martin Flack: Physiological Aspects of Flying (2).

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith.

MONDAY, March 26th.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Dr. Trevor Davies: Gynæcological Department. 2 P.M., Dr. Ironside: Medical Out-patients.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M. Mr. Hamblen Thomas: Throat, Nose, and Ear Department. 2 P.M., Mr. Addison: Operations.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M. Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 3 P.M., Sir Henry Simson: Gynæcological Ward.

FRIDAY.—10 A.M., Dr. Pritchard: Medical Wards. 12 noon Dr. Ironside: Clinical Demonstration. 2 P.M., Mr. Vlasto: Throat, Nose, and Ear Department.

SATURDAY.—9.30 A.M., Dr. Burnford: Bacterial Therapy Department. 10 A.M., Dr. Owen: Medical Diseases of Children.

Daily, 10 A.M. to 5 P.M., Saturdays, 10 A.M. to 1 P.M. In-patients, Out-patients, Operations, Special Departments, Anæsthetic and Operative Surgery Classes.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, March 29th.—4 P.M., Mr. A. T. Pitts: On Hygiene.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, March 26th.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

FRIDAY.—10.30 A.M., Throat, Nose, and Ear Clinics. 2.30 to 5 P.M., Surgical, Medical, and Children's Diseases Clinics. Operations.

On Tuesday, at 2.15 P.M., and Thursday, at 2.30 P.M., there will be special demontrations of Medical and Surgical Cases by Dr. F. G. Crookshank and Mr. H. W. Carson respectively.

FELLOWSHIP OF MEDICINE AND POST-GRADUATE MEDICAL ASSOCIATION, 1, Wimpole-street, W.

MONDAY, March 26th, to SATURDAY, March 31st.—HAMPSTEAD GENERAL HOSPITAL, Haverstock Hill, N.W. Practitioners' course in medicine, surgery, and the specialties. Mon. to Fri., 4.30 to 6 P.M., lecture and demonstration.—ROYAL NATIONAL ORTHOPÆDIC HOSPITAL, Great Portland-street, W. All day course—clinics, operations, and lectures.—Further particulars from the Secretary, Mayfair 2236.

LONDON SCHOOL OF DERMATOLOGY, St. John's Hospital, 49, Leicester-square, W.C.

TUESDAY, March 27th.—5 P.M., Dr. A. C. Roxburgh: Scleroderma. Neurofibromatosis.

THURSDAY.—5 P.M., Dr. A. C. Roxburgh: Diseases of the Nails.

CENTRAL LONDON THROAT, NOSE AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY, March 30th.—4 P.M., Mr. Archer Ryland: The Musculature of the Vocal Cords.

PEOPLE'S LEAGUE OF HEALTH.

FRIDAY, March 30th.—6 P.M. (at the Medical Society's Rooms, 11, Chandos-street, Cavendish-square, W.), Mr. Eric Holmes: Common Errors in Daily Life.

CHADWICK PUBLIC LECTURES.

FRIDAY, March 30th.—8.15 P.M. (at the Royal Institute of British Architects, 9, Conduit-street, W.), Dr. R. E. Stradling, Assoc.M.Inst.: Balbus Built a Wall. (Blossom Gift Lecture.)

MANCHESTER POST-GRADUATE LECTURES, Mill-street, Manchester.

THURSDAY, March 29th.—4.15 P.M., Mr. P. G. McEvedy: Treatment of Thyroid Adenomata.

MANCHESTER ROYAL INFIRMARY POST-GRADUATE COURSE.

TUESDAY, March 27th.—4.15 P.M., Mr. P. R. Wrigley: Intestinal Obstruction.

FRIDAY.—4.15 P.M., Mr. H. H. Rayner: Demonstration of Surgical Cases.

Appointments.

Queen Charlotte's Maternity Hospital: Ross, G. A., M.B., Ch.B. Aberd., Senior Resident Medical Officer; LOWRY, H. C., M.B., Ch.B., F.R.C.S., Assistant Resident Medical Officer; MORGAN, Miss G. M. B., M.B., B.Ch., District Resident Medical Officer.

Certifying Surgeons under the Factory and Workshops Acts: HUGHES, L. E., L.R.C.P. Lond., M.R.C.S. (Cirencester); JONES, T. E., L.R.C.P. Lond., M.R.C.S. (Aberayron, Cardiganshire); and MCINTOSH, J. W., M.B., Ch.B. Edin. (King's Lynn, Norfolk).

Vacancies.

For further information refer to the advertisement columns.

Ashton-under-Lyne, District Infirmary.—H.S. At rate of £150.
Barbados Lunatic Asylum.—Asst. Med. Supt. £500.
Belgrave Hospital for Children, Clapham-road, S.W.—H.S. and Asst. H.P. Each at rate of £100.
Brighton, New Sussex Hospital.—H.S. At rate of £50.
Bristol, Southmead Hospital.—Consultant to Ear, Nose and Throat Dept. £100.
Burnley, Victoria Hospital—H.P. At rate of £125.
Bury Infirmary.—Third H.S. At rate of £150.
Cambridge, Addenbrooke's Hospital.—H.S. At rate of £130.
Cardiff Royal Infirmary.—Gynæcological H.S. At rate of £50, and Ophth. H.S. At rate of £75.
Charing Cross Hospital.—Surg. Reg. £150. Also Asst. Surg.
Croydon Union, Mayday-road Hospital.—Res. Asst. M.O. £300.
Dudley, Guest Hospital and Eye Infirmary.—Asst. H.S. £150.
Dublin, City Skin and Cancer Hospital.—Res. H.S., &c.
Evelina Hospital for Children, Southwark, S.E.—H.S. At rate of £120. Also Med. Radiographer. £120.
Folkestone, Royal Victoria Hospital.—Sen. and Jun. Res. M.O.'s. At rate of £150 and £100 respectively.
Galway University College.—Professorship of Therapeutics, &c. Also Midwifery. Each £308–£320.
Hong-Kong.—Two Asst. M.O.H.'s. Each £740.
Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each £50.
Indian Medical Service.—Commissions.
Lanark County.—Asst. M.O. £500.
Liverpool Heart Hospital.—Hon. Asst. Phys.
Liverpool, Waterloo and District General Hospital.—Res. H.S. £50.
London Temperance Hospital, Hampstead-road, N.W.—Surg. Reg. 40 guineas.
Lucknow University.—Professor of Anatomy. Rs.1450 per mensem.
Melbourne, Victoria, Australia, Children's Hospital, Frankston.—Med. Supt. for Orthopædic Section £1000.
Miller General Hospital for South-East London, Greenwich-road, S.E.—Hon. P. to Children's Spec. Dept.
Ministry of Health, Whitehall, S.W.—Deputy Regional M.O. £800.
Nottingham General Dispensary.—Res. Lady Surg. £250.
Paddington Green Children's Hospital, London, W.—H.P. and H.S. Each at rate of £150.
Prince of Wales's General Hospital, Tottenham, N.—H.S.'s and H.P., also Jun. H.S. and Jun. H.P. At rate of £120 and £90 respectively.
Princess Louise Kensington Hospital for Children, West Kensington, W.—H.P. and H.S. At rate of £100 and £75. respectively.
Queen's Hospital for Children, Hackney-road, E.—P. in charge of Skin Dept.
Rochdale Infirmary and Dispensary.—Jun. H.S. £200.
Royal Free Hospital, Gray's Inn-road, W.C.—Cas. O. £150. Also Res. Anæsthetist.
Wakefield, City of.—Deputy M.O.H. £625.

The Chief Inspector of Factories announces vacancies for Certifying Factory Surgeons at Westerham (Kent), Aberchirder (Banffshire), Rhynie (Aberdeenshire), Tyldesley (Lancashire) and Fakenham (Norfolk).

The Home Secretary gives notice that he proposes to appoint a medical referee or referees under the Workmen's Compensation Act for the districts of the Northampton and Towcester, Newport Pagnell, and Leighton Buzzard County Courts (Circuit No. 23). Applications are invited from duly qualified medical practitioners resident at or near these centres, and should be addressed to the Private Secretary, Home Office, Whitehall, S.W. 1, on or before April 7th, 1928.

In consequence of the resignation, as from the 30th prox., of Dr. A. S. Percival, Newcastle-on-Tyne, Ophthalmic Specialist Medical Referee under the above Act for all County Courts in Circuits 1 and 2 (Northumberland and Durham), the appointment held by him will become vacant. Applications for the post should be addressed to the Private Secretary, Home Office, Whitehall, S.W. 1, and should reach him not later than April 11th, 1928.

Births, Marriages, and Deaths.

BIRTHS.

BICKERTON.—On March 17th, at Welbeck-street, the wife of J. Myles Bickerton, F.R.C.S. Eng., of a daughter.

HITCHCOCK.—On March 15th, at Harrogate, the wife of Dr. C. G. Hitchcock, of a son.

PARSONS.—On March 14th, at Wellington-road, St. John's Wood, the wife of Dr. R. A. Parsons, of a son.

MARRIAGES.

LAING—JOHNSTON.—On March 17th, at St. Anne's Church, Corstorphine, David Laing, M.B., Ch.B., to Hilda Katharine, youngest daughter of the late James Johnston and Mrs. Johnston, Corstorphine, Mid Lothian.

SIMPSON—CARTER.—On March 17th, at St. Mary's Church, Melton Mowbray, John Whitwell Hope Simpson, M.R.C.P. Lond., to Florence Mable, younger daughter of Mrs. Carter, of Melton Mowbray.

DEATHS.

FERRIER.—On March 19th, at York House, Church-street, Kensington, W., Sir David Ferrier, M.D., LL.D., F.R.S., in his 86th year.

KILNER.—On March 15th, at Northgate-street, Bury St. Edmunds, Henry Goff Kilner, Croix de Guerre, M.B., B.S., M.R.C.S., L.R.C.P.

KINKHEAD.—On March 18th, at Forster House, Galway, Prof. Richard John Kinkhead, M.D., in his 83rd year.

MAYNARD SMITH.—On March 18th, at Wimpole-street, W., Sidney Maynard Smith, Colonel, A.M.S., C.B., Croix de Guerre, Kt. of Grace of the Order of St. John of Jerusalem, M.B., B.S., F.R.C.S., aged 52.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

INTERNATIONAL MEDICAL GROUP FOR THE INVESTIGATION OF BIRTH CONTROL.

LAST September, in the course of a Conference on World Population, held at Geneva, medical representatives of different countries interested in the subject of birth control met informally and decided to form an international medical committee with the objects of coördinating biochemical, physiological, and statistical research bearing upon contraception, and of broadcasting the knowledge so obtained. By this means it is hoped to establish an informed and enlightened attitude to birth control through the medical professions of the different countries. The activities of the committee are to be limited to statistical investigations on the reliability, simplicity, and harmlessness of different contraceptives; immunological, biochemical, or physiological research work on the problems of contraception and sterility, and information on the general attitude of a country towards birth control. The headquarters are to be in England and the committee is to be essentially a medical information bureau and non-propagandist.

Invitations were sent out at the beginning of December for contributions to the first report and three replies were received, which constitute the first quarterly review. Dr. Leunbach (Denmark) reports that he has gradually given up the use of the cervical pessary, which is only suitable for 5–10 per cent. of women. It requires a stud-shaped cervix and a rather tight vagina, and very few women can apply it correctly themselves. He now uses only the Dutch pessary with watch-spring rim, such as is sold in this country as the "Lambert" or "Norman Haire" pessary. It took his manufacturer half a year to find just the right kind of spring, which must be neither too tight nor too slack. The spring used is an unheated Swiss watch spring and the cost about 3*s*. A good pessary should last a year or more. In order that a pessary should be easy to insert and held firmly in position in the vagina it must be large in size, and Dr. Leunbach has now made it his rule to use the largest that can without inconvenience be placed in the vagina, usually between 75 and 82 mm. in diameter. He quotes a case where a No. 75 managed to lie with its anterior rim in the recess below the symphysis and its hinder rim still in front of the cervix, so that conception occurred. Most of the failures he has seen have occurred because the pessary was many sizes too small. In the year 1926–7 he fitted 800 pessaries and only had three failures. He has seen no case where the pessary has done any harm or has reduced sexual enjoyment. He has come to the conclusion, after careful experiment, that all contraceptive suppositories are practically worthless. For the douche water he recommends chinosol, or tablets made of trypaflavine and boric acid of each 0·02 g., but any harmless substance will serve.

The official attitude to birth control in Denmark is a passive hostility, but there is no legal opposition, and public and medical opinion is gradually coming round to the practice. In Sweden, Dr. Alma Sundquist reports, the general attitude of the doctors is enlightened and tolerant, and the law against public information about contraceptives is hardly ever enforced. In Germany, according to Dr. H. Riese, the teaching of birth control is regarded as contrary to medical honour, and not even the gynæcologist is taught contraceptive methods. At his clinic he recommends a gelatin suppository containing quinine, boric acid, and lactic acid, placed against the cervix immediately before the introduction of the rubber cap. On the morning after use, the woman is instructed to irrigate with potassium permanganate or lactic acid. He has had no failures in the several hundred cases he has seen in the last two years.

The review concludes with an account of the position in England by Dr. C. P. Blacker, taken from the annual reports of the Ministry of Health 1926–7, and of the Walworth Women's Welfare Centre, 1926–7, the works of Dr. Marie Stopes, and two books published by the National Council of Public Morals—viz., "The Ethics of Birth Control" (Macmillan) and "The Medical Aspects of Contraception" (Martin Hopkinson).

A SATISFACTORY MICROSCOPE.

WE are informed that the London School of Hygiene and Tropical Medicine has placed an order with Messrs. R. and J. Beck, Ltd., for over two hundred microscopes for use in the laboratories now under construction in Gower-street. The order has been given on the recommendation of a small committee, which has been considering the matter for some time in consultation with the Department of Applied Optics, National Institute for Medical Research. The type of microscope selected embodies features that have been evolved to meet the needs of the heads of departments at the school. Its base is of rigid construction with points of support sufficiently wide spread to ensure stability in any position. The foot is of the type now being produced by Messrs. Beck combining the advantages of the horse-shoe or Continental model with the so-called English foot. The stage is of the completely built-in mechanical type with travel of 1½ in. + 1 in., the entire top plate of the stage forming the moving part. On the stage a slide-holder of new design is provided, in which the slide is firmly held without springs. The fine adjustment is of the double-lever pattern, operated by milled heads on either side. The body is 2 in. in diameter and is provided with an adjustable graduated drawtube. The substage is actuated by rack and pinion, and all substage appliances are carried on Akehurst slides. Thus, the interchange of illuminating systems is both easy and accurate. The optical equipment is ample for all bacteriological requirements, and the objectives are to be coloured externally so as to enable them to be recognised at sight. Messrs. Beck have agreed that certain rigid tests shall be applied to the whole equipment before delivery is accepted.

THE "HELSAN" TUBERCULOSIS DEMONSTRATION IN SWEDEN.

As long ago as 1904 an elaborate scheme was devised by the Swedish National Association against Tuberculosis for solving the tuberculosis problem on a small scale in an isolated country area. The working of this scheme is the subject of a long paper in English, in *Acta Tuberculosea Scandinavica*,[1] by Dr. G. Neander, Secretary General of this Association. The area chosen was in the north of Sweden, and early in 1906 a whole-time specialist in tuberculosis was appointed together with two nurses. A building was purchased to serve as a combined cottage hospital, children's home, and doctor's residence. A wholesale examination of the population in 1906 was repeated in 1908, with the result that 12 per cent. of the total population examined in 1908 were found to be suffering from pulmonary tuberculosis. By the addition of 33 cases of surgical tuberculosis, the total incidence of tuberculosis in the population examined was brought up to 14 per cent. The campaign for reducing this tuberculosis-rate was conducted on lines familiar to every tuberculosis worker. When children could not be removed to the cottage hospital from tuberculous homes, every effort was made to reduce the exposure to infection in these homes to a minimum. All the 22 healthy children removed from tuberculous homes to the "Helsan" Home were found, in 1914, to be in excellent condition. An educational campaign was directed to abolishing, among other things, the old-fashioned cupboard beds in which two or more persons used to sleep almost hermetically sealed up. When, in 1926, another wholesale examination was made, it was found that the incidence of pulmonary tuberculosis had fallen from 12 to 8 per cent. and the total incidence of all forms of tuberculosis from 14 to 9·5 per cent. As for the tuberculosis mortality, it was found that this had declined from 8·3 per thousand in the five-year period 1911–1915, to 6 per thousand in the five-year period 1921–1925—i.e. a fall of 28 per cent. This fall was the more striking, as the fall in the tuberculosis death-rate in the district of which the experimental area is a part was only 0·5 per cent. Indeed, while the tuberculosis death-rate had fallen dramatically in the experimental area, it had actually increased in the adjoining areas.

M.D.—The first passage will be found in Pantagruel, Bk. II., c. vii. The exact quotation from Rabelais is: Quæstio subtilissima: utrum Chimæra, in vacuo bombinans possit comedere secundas intentiones? It purports to be an entry in the catalogue of books in the library of St. Victor in Paris. The second reference, also ribald when completed, is to a passage in the Summa Theologiæ: An plures angeli possint esse simul in eodem loco? Non, quia non possunt esse duæ causæ completæ unius effectus. Both authors would be likely to be quoted in a mediæval medical work.

BOARD OF EDUCATION: MEDICAL BRANCH.—The Medical Branch of the Board will be transferred from 54, Victoria-street, London, S.W. 1, to the Board's main office in Whitehall, on April 2nd, and correspondence from that date should be addressed to the Secretary, Board of Education (Medical Branch), Whitehall, London, S.W. 1. The telegraphic address will be "Meducation, Parl. London," and the telephone number, Victoria 9800.

Goulstonian Lectures

ON

SOME PROBLEMS OF NEPHRITIS.

The Second Goulstonian Lecture in 1928 delivered before the Royal College of Physicians of London on March 15th

BY T. IZOD BENNETT, M.D. LOND.,
FELLOW OF THE COLLEGE; PHYSICIAN TO OUT-PATIENTS, MIDDLESEX HOSPITAL, AND TO THE ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.

LECTURE II.*—THE PROBLEM OF ŒDEMA.

"When albumen is proved to exist in the urine I look upon it with anxiety, and the confirmed derangement I always view with dread."—R. BRIGHT, Goulstonian Lectures, 1833.

I CONCLUDED my previous lecture with a quotation from Bright, in which he expressed the opinion that an increase in the urea of the blood was at least a partial explanation of the phenomena which we group together as uræmia. When we consider the difficulties of blood analysis, this observation becomes a very wonderful one, but we recognise to-day that it is at least improbable that the accumulation of nitrogenous substances in the blood is an actual cause of uræmia, however useful an index these substances may be of the imminence of such a catastrophe.

In this lecture I am going to discuss the problems of the so-called "renal" œdema, a subject of even greater complexity than that of uræmia. The work of the chemical and experimental laboratories has advanced to a degree that makes it quite impossible for any man to form a useful judgment on such subjects from the result of his personal observation alone, and the intricacy of many of the researches into œdema is such that the wheels of the intelligence become almost clogged in the effort of sifting the important from the insignificant facts; but I believe that close study leads one to the conclusion that when œdema occurs in a case of nephritis it is evidence of the existence of an extra-renal factor which may explain the nephritis, but is never the consequence of nephritis. We speak of "renal" œdema, and we are accustomed to look on nephritis as one of the common causes of œdema, but I am sure that we should be very hesitant in adopting such a view. The time has certainly not yet come when any man can claim to understand with full clarity the mechanism of œdema, but I believe that if the existing data are carefully and logically examined the balance of evidence to-day is against œdema ever being the direct consequence of disease of the kidney, though it is possible that the cause of the œdema may also provoke disease of the kidney.

THE VIEWS OF BRIGHT.

It is, I think, accurate to say that Bright's most famous work directed the attention of the world to the association between albuminuria, œdema, and disease of the kidneys, and it is perhaps an excessive piety which has made many of his successors cling to the notion that such œdema is a necessary consequence of nephritis. I say an excessive piety because examination of Bright's actual words reveals the same dislike for dogmatism regarding this problem that we find in his expressed opinion on so many subjects. In his Goulstonian lectures he said:—

"My conviction is complete as to the existence of some undivided connection between the three facts—anasarca, scanty urine, and diseased function going on to diseased structure of the kidney. How these facts are connected or what necessary dependence the one may have upon the other, it is indeed difficult to point out, and some might suppose that we are rather perverting the order of events when we speak of the condition of the kidneys as causing anasarca";

but it is clear from the succeeding lines that his own opinion was in favour of the theory that œdema in nephritis is due to the disease of the kidneys.

If we follow the life-work of another great pioneer of internal medicine, Claude Bernard, we cannot, I think, fail to be impressed by the fact that his conviction that the mystery of diabetes mellitus was to be solved by a fuller understanding of hepatic disturbance not only wasted months of his own time, but led to many of his countrymen subsequently wasting years through too pious a belief in the infallibility of the master. The more carefully we read the works of Bright, the more must we be impressed by his caution in avoiding dogmatism; nor must we fail to note that occasionally, when dogmatic, he was wrong. Prof. W. S. Thayer, of Baltimore, in an inspiring oration delivered last year at Guy's Hospital, recalled to his audience the fact, for example, that Bright stated that chorea was often the result of pericarditis. But on the question of the œdema seen in nephritis Bright was more cautious, and though he formulated his personal opinion he did so with reserve.

THE MAIN SYNDROMES OF NEPHRITIS.

It is now common knowledge that when cases of nephritis are examined from the clinical point of view there are many which stand out clearly owing to the presence of certain main features and a corresponding absence of other signs and symptoms. In my previous lecture I selected a case of cystic disease as illustrating in this manner uræmia without œdema. It is not more difficult to find cases where œdema and albuminuria are similarly conspicuous and uræmia and nitrogen retention absent. In Table I. I have set

TABLE I.

Marked.	Albuminuria.	Slight.
,,	Œdema.	Absent.
Absent.	Cardiac hypertrophy and hypertension.	Marked.
,,	Nitrogen retention.	,,
,,	Tendency to uræmia.	,,
Normal.	Urea in urine.	Low concentration.
Normal or diminished.	Amount of urine.	Polyuria or suppression.
Normal.	Specific gravity of urine.	Low.

out the main features of cases of renal disease, placing in the columns on either side the characteristics of the two extreme types which diverge from the main general picture. These contrasting types constitute the hydropiginous and azotæmic nephritis of French writers and are often referred to in British and American writings under similar titles. It is, as I have said, quite easy to secure examples of either class, but to explain how disease of the kidney can produce results so entirely divergent is excessively difficult.

An explanation was at last offered by the theory of Widal, who, working with Javal in the early days of the present century, put forward the hypothesis that nephritis might affect the kidney in such a manner as to interfere either: (*a*) with its power of excreting urea and kindred nitrogenous substances, or (*b*) with its power of eliminating salts of which sodium chloride is the most important. Cases of albuminuria with œdema, of the type to which long custom in this country has given the name of "chronic parenchymatous nephritis," were thus explained as being examples of a derangement of the capacity of the kidney to excrete sodium chloride without interference with the excretion of urea and other nitrogenous bodies.

THE THEORY OF SALT RETENTION.

This view, which I gather from a very recent article by Lemierre to be still current, is founded chiefly on the fact that the administration of salt to patients with so-called renal œdema is followed by an increase in the œdema and a failure of the salt to appear in the urine. And the successful reduction of œdema by means of salt-free diets in some cases is held to be strong confirmation of the theory. But if the salt retention is due to failure on the part

* Lecture I. appeared on March 17th.

of the kidney, we should find an increase in the blood-chlorides, and this has never been demonstrated in these cases. Moreover, it is now generally agreed that diminished excretion of sodium chloride is even more marked in the case of diseases such as cardiac failure and lobar pneumonia, where the renal function is not interfered with. When one proceeds from this to point out that the same kidneys which at first secreted a urine poor in chlorides will a week later, when œdema is subsiding, secrete a urine containing abundant chlorides, it becomes increasingly probable that the retention of salt is due to some extra-renal cause, or that, in the striking phrase of Fishberg, there has been a " pre-renal deviation " of both water and chloride, or, in other words, that these substances have been diverted into the tissues without the kidneys having had an opportunity of excreting them.

We know to-day that salt-free diets are of uncertain utility in œdema, but that on the whole they are more likely to be effective in cases of cardiac failure than in cases of so-called nephritic œdema. The salt-retaining kidney must, I fear, be dismissed as a myth as far as it may serve as an explanation of œdema, for, if there is any type of kidney which is capable of retaining salt, it is not that associated with œdema, but rather the kidney where extreme destruction has led first to nitrogen retention, and, last of all, to retention of bodies such as sodium chloride which are normally not greatly subjected to concentration in their passage from blood to urine. Table II. shows the degree of

TABLE II (*after Fishberg*).

Substance.	Concentration in—		No. of times concentrated.	In renal insufficiency.
	Urine.	Blood.		
Urea	2000	30	65	Increased.
Creatinine ..	75	2	35	,,
Phosphate ..	150	3	50	,,
Chloride ..	500	350	1·5	Not increased.
Calcium ..	15	10	1·5	,,

concentration undergone by certain of the commoner substances in the urine as opposed to their state in the blood. A short study of the figures in the third column gives the clue to the problem as to why some constituents, such as urea and phosphates, are so notably increased in the blood of all patients with renal impairment of high degree, for it is surely natural that the greatest difference will be found in those substances which are normally most concentrated by the healthy kidney. But with the final stages of renal impairment, even these bodies which are concentrated but slightly by the normal kidney become affected, and then, as de Wesselow and others have shown, an increase in the chlorides of the blood becomes apparent and may be demonstrated by means of salt test-meals.

The most marked examples of such retention are found in mechanical obstruction. Braasch has recorded a case of obstruction to both ureters where the blood chlorides reached the extreme figure of 1500 mg. per 100 c.cm., and Fishberg has observed a case where the figures rose to 1000 mg. In uræmia following nephritis the concentration of blood chlorides does not often approach such heights, but an increase above the normal is probably always present in the terminal stages. We must, on the other hand, note that in such cases with high concentration of chlorides in the blood œdema is often conspicuously absent. If now we summarise the facts concerning chloride retention in nephritis, we can, I think, draw three important conclusions :—

1. That in cases of " renal " œdema there may be evidence of accumulation of chlorides in the watery subcutaneous tissues, but there is no evidence of chloride retention in the blood.

2. That there are cases of renal disease in which retention of chlorides in the blood is present, but such cases do not as a rule exhibit œdema.

3. That it is, therefore, probable that the accumulation of chlorides in the œdema fluid is due to an extra-renal factor.

AN ILLUSTRATIVE CASE.

From these theoretical considerations it will no be well to turn to a particular case illustrative so-called renal œdema, a case selected on account the absence of nitrogen retention and cardiovascul features.

The patient, a man aged 22, has been under my ca during the last 18 months. His early history was of insigni cant childish ailments—measles, chicken-pox, and whoopin cough having affected him, but all slightly. Five years a he had a trivial attack of pleurisy, and three years ago w troubled with a transient skin eruption. In the summ before last, during a holiday at a time when his heal appeared to be excellent, he observed one day after bathi that his abdomen and legs were swollen. A few weeks lat he noticed this swelling in the face, and became troubl with a transient epigastric pain, accompanied after a fe days by diarrhœa. He noticed nothing the matter with h urine.

In the late autumn of 1926 he consulted me at the Middles Hospital, when he was suffering from an obvious œdem of the legs and lumbar region, together with some puffine of the face. Ascites was present, and there was evidence bilateral hydrothorax. The blood pressure was 140/9 the heart apparently normal. After two days in bed t blood pressure was found to be 100/70. The optic fun were quite normal, the urine had a specific gravity of 102 and contained large amounts of albumin, together with a fe hyaline and granular casts, but no blood. The Wasserma reaction was negative, and analysis of the blood gave norm figures as regards nitrogenous constituents and chlorides.

He was admitted to the Middlesex Hospital under t care of my senior colleague, Dr. C. E. Lakin, and was p on a diet containing abundant protein and no fat. T urine was found to vary in volume between one-third a three-quarters of a litre per diem. The daily albumin lo amounted to as much as 10 g. or more. Repeated blo analyses confirmed the normal nitrogen figures. The se mentation time of the red corpuscles was considera diminished, and the basal metabolic rate was 19 per ce below normal. The urea in the urine varied between 2 a 3 per cent., and, after the administration of 15 g. of ur rose to just about 3, showing full concentrating pow In addition to the generous protein diet, he was given ur in doses of 60 g. or more daily, and in a few weeks t œdema of the legs, face, and lumbar region complet disappeared, although there remained evidence of slig ascites. The daily albumin loss remained high, but t patient felt quite well in himself throughout the treatme He has been seen at regular intervals during the subsequ 12 months, and though his œdema has fluctuated and nev entirely disappeared it has never reached a degree sufficie to make him abandon his work. The albuminuria has alwa been excessive. He has, from time to time, been giv thyroid extract, and shows a marked tolerance for t substance, but I have been unable to observe any defin influence thereby exerted on his general state.

NEPHROSIS.

Cases of this type are, one gathers, typical of th group which it is now fashionable to describe unc the title of " nephrosis," a word apparently fi suggested by Müller and since adopted very wide especially in the United States by Epstein and othe and in Germany by Volhard and Fahr, Munk, a their followers. The word is ambiguous, in itself conveys no clear concept, and a study of the literatu reveals that it is used with a different connotati by different writers. In a paper published in co junction with E. C. Dodds and D. T. Davies last ye an endeavour was made to define the prevalent vie on the subject. We wrote :—

" According to the conception of Munk, all renal disea with œdema, apart from heart failure, should be classed nephrosis, whilst cases with hæmaturia, uræmia, and card vascular complications constitute true nephritis. Wher waterlogged patient gets an attack of hæmaturia, and blood pressure rises and nitrogen retention appears, it nephritis complicating nephrosis ; when, on the other ha a patient after a febrile hæmaturia with transient hyperpie passes into a condition of anasarca, that is nephrosis sup vening upon nephritis. It must be noted that in contr to these views many British pathologists hold that ætiology of all kidney disease is toxic, degeneration be always the first effect and reaction a later, but not inevitab consequence, and that degeneration is itself an inflammato phenomenon, whether followed by reaction or not."

I am interested to note that a recent essay by su an authority as Prof. Ludwig Aschoff confirms wh

have quoted as being a correct interpretation of the German view. He writes :—

"The meaning of this word has given rise to many differences of opinion in the past decades. . . . We understand it to mean those diseases of the kidneys which are characterised chiefly by degenerative changes of the tubular apparatus," and later, "the characteristics of Volhard's nephrosis, in the strict sense, are marked œdema and the excretion of much albumin in the urine, absence of the least increase of blood pressure, and, therefore, also of the slightest hypertrophy of the heart."

The case I have presented may, therefore, be accepted as a typical example of nephrosis, and it is further typical of this group in that the patient exhibits the lipæmia which is, I believe, characteristic of all cases of pure nephrosis, and present in the vast majority of examples of "renal" œdema of all classes.

Biochemical Aspects of Nephrosis.

The biochemical investigation of cases such as the one I have dealt with yields results which are largely negative: (*a*) The total daily volume of the urine is somewhat reduced when observed over any long period, but its urea-content is high during periods when one would expect it to be high. The specific gravity is consequently normal in its variations. Blood is absent, and the only casts are hyaline or granular. The notably abnormal constituents are albumin and certain lipoid substances which can be recognised by their double refractive properties when the centrifuged urine is examined by a microscope fitted with a polariscope. (*b*) The blood is normal as regards the nitrogenous substances and salts in solution, but is abnormal in that it almost invariably contains an excessive amount of cholesterol. Examination of the blood proteins shows that the normal proportion of albumin to globulin is reversed. (*c*) The basal metabolic rate is usually considerably lower than the normal.

Of these various findings the most striking is excessive cholesterol in the blood, which is incidentally almost certainly the explanation of the doubly refractive lipoids found in the urine. In Table III. are given the results of the estimation of cholesterol in the blood of the patient I have described at different periods. It will be observed that they are almost invariably high when compared with the normal.

Table III.

Date.	Blood-urea.	Blood cholesterol.	Œdema.
October, 1926 ..	—	209	—
November, 1926 ..	20	246	—
December, 1926 ..	19	294	Better.
January, 1927 ..	26	117	—
March, 1927 ..	23	348	Worse.
April, 1927 ..	29	528	Better.
December, 1927 ..	79	188	Much better.
March, 1928 ..	75	244	No œdema.

The subject of the blood cholesterol in nephritis has recently been carefully investigated by J. Maxwell in a large series of cases at St. Bartholomew's Hospital. He confirms the results of the numerous observers which Dodds, Davies, and I summarised in the communication already referred to. Maxwell found that an increase in the plasma-cholesterol is almost invariably associated with every type of renal œdema, and that though in chronic cases the actual height of the cholesterol figures is not necessarily proportional to the degree of œdema, its presence is evidence that the case will run a chronic course. He further concludes that renal œdema and the increased plasma-cholesterol are not related as cause and effect, but that both are probably the result of some toxic disease acting upon the cells of the reticulo-endothelial system.

As regards the reduced basal metabolic rate in cases of pure nephrosis, this factor has been stressed by Epstein, to whom we owe in such a large measure our knowledge of this group of cases. I have not personally experienced the success from the use of thyroid extract which he has claimed, and a good point of criticism is made by Murphy and Warfield, who point out that the water retention in the tissues of these patients gives them an illusive weight which renders estimation of the basal metabolism very difficult.

Pathological Aspects of Nephrosis.

It is not easy to speak with exactitude concerning the morbid anatomy of cases of lipoid nephrosis for the simple reason that they are seldom fatal, but run a very chronic course. It is indeed doubtful whether death ever occurs except as the result of some complicating or intercurrent disease. It is in this respect worthy of note that the termination is not infrequently due to a form of chronic peritonitis, possibly of pneumococcal origin, and perhaps due to accidental infection of the ascitic fluid. Cases of this type were included in a series reported by Dyke and have frequently been referred to by German authorities. When the kidneys of such a patient are secured, they are found to contain enormous quantities of cholesterol in the cells of the tubules and have the typical greasy appearance which has led to their being designated "myelin" kidneys. This condition was first described in 1902 by Kaiserling and Orgler, and examples have been demonstrated by McNee and others in this country. Through the kindness of my colleagues, Prof. James McIntosh and Dr. Lakin, I am able to show you a specimen this afternoon.

The histological characteristics of such kidneys are: (*a*) degenerative changes, usually confined to the tubules where the cholesterol esters are found in great profusion; (*b*) glomerular tissues little, if at all, damaged.

Rarity of Pure Lipoid Nephritis.

The number of cases in which it is possible to speak of a pure lipoid nephrosis is certainly limited. Elwyn, who has made important contributions to this subject, believes that in all cases there is an initial glomerulo-nephritis which often heals, leaving tubal damage which has resulted from the absorption of the pathological glomerular transudate. Against this view must be put that of Murphy and Warfield, who have actually been able to demonstrate the kidneys of a case in which not the slightest evidence of a glomerular lesion could be found. In cases such as the one I have described I find no evidence that there was an initial lesion affecting the glomeruli, and the opinion of Epstein and of the German physicians is also to this effect.

But we may, on the other hand, accept the possibility of a primary pure nephrosis, without suggesting that such a kidney may not easily undergo secondary damage of greater degree. An organ which is choked with cholesterol should from that fact alone be more readily susceptible to damage than is a normal organ. Or, if we examine the prognosis of such cases from the point of view of the possible effects of the prolonged hypercholesterolæmia, it is not necessary to suggest that such a blood condition is the result of renal damage, there is, indeed, no evidence for such a view, nor must it be assumed that the excess of blood cholesterol will produce a nephritis; we know, on the contrary, that patients with diabetes, or jaundice, or xanthoma may have hypercholesterolæmia for years without signs of kidney damage. We do know, on the other hand, that arterial lesions such as atheroma can readily be produced by cholesterol-feeding in animals; Scarff, in a recent series of experiments, has fully confirmed previous observations to this effect, and the work of Labbé and Heitz tends to show that the hypercholesterolæmia of chronic diabetes may be accompanied by such vascular changes that a very adverse effect on the general circulation, including the blood-supply to the kidneys, is to be expected.

There are, therefore, several reasons why cases of apparently pure lipoid nephrosis may subsequently develop signs of renal failure, and such a development is by no means incompatible with a primary condition

in which these features were completely absent. In the case I have described, for example, there appears during the last six months to have been a certain evolution which is perhaps ominous. The blood-urea and non-protein nitrogen have risen from their original normal level to figures which approach the low limits of the pathological. In addition to this, there seems to be a very slight, but definite, progressive elevation in the blood pressure, and if continued observation confirms these findings, we must, I believe, conclude that there is progressive change going on in the kidney. But even accepting such a development as the fate of a number of these cases, there remains a proportion in whom such an evolution never occurs, and we may, I think, draw certain conclusions from them, namely:—

1. That the only clinical evidence of nephritis presented by them is albuminuria.
2. That the balance of evidence is against the hypercholesterolæmia being an effect of renal damage.
3. That it is difficult to harmonise the localised histological appearances of the kidneys in these cases with the theory that this is a true primary renal disease.

Is Œdema the Result of Albuminuria?

Returning now to the problem of œdema, the question at once arises whether either the hypercholesterolæmia or the albumin-loss found in lipoid nephrosis will furnish the explanation of the œdema so conspicuous in these cases. As regards cholesterol, I have already pointed out that it does not appear to be the result of a renal lesion, but is rather the cause of the main renal abnormality. And when we inquire what relation it may have to the œdema, we are faced with two facts: (1) that in cases of hypercholesterolæmia due to jaundice or diabetes, there is usually no œdema, and (2) that, as Maxwell has shown, the cholesterol in "nephritis" does not vary in proportion to the œdema, and, therefore, these two features can scarcely be cause and effect.

When we examine the possible relation between the œdema and the albuminuria, we become concerned with the views of Epstein, whose work on lipoid nephrosis must rank as one of the great advances of recent years. For not only was this observer the first to describe fully the features characteristic of this disorder, but we owe very largely to him our present knowledge that high protein feeding is desirable in its treatment. Epstein's views are further remarkable in that he is almost alone in having put forward a plausible theory to explain œdema as a direct effect of a renal lesion. His view, if I have correctly understood him, is that the continued albuminuria causes such a depletion of albumin from the blood plasma that the normal proportion of albumin to globulin is eventually reversed. This brings about a lowering of the osmotic pressure in the circulating blood, and there is a consequent passage of water from the circulation to the tissues where the osmotic pressure is higher. Epstein's diet was specially chosen in an endeavour to replace as far as possible the albumin depletion by means of a generous supply of appropriate proteins in the food, and the frequent success of this diet lends apparent support to his theory of the mechanism of œdema. But in spite of its attractiveness this hypothesis has failed to convince the majority of the physiologists interested in the subject. It is clearly not possible to utilise such a theory to explain those types of œdema which follow starvation or faulty diet, or the œdema produced in inflammation and other pathological conditions, apart from circulatory failure, and it is perhaps on this account that the theory has found so little favour with the physiological school above referred to. Further, it is apparently difficult on the basis of this theory to explain the actual chemical composition of the œdema fluid; on the other hand, consideration of the writings of the pure physiological and pathological schools inclines one to the belief that they have perhaps not recognised the close association always encountered in clinical work in renal cases which exhibit both œdema and albuminuria.

When cases with cardiac œdema are carefu excluded, it is certainly very difficult to find a case so-called renal œdema in which albuminuria is no very marked feature, but I think that close inqui amongst cases of nephritis in pregnancy and acu glomerulonephritis always leads to the discovery an appreciable proportion of cases in whom the œde is out of all proportion to the daily amount of albun lost. If, on the other hand, we examine cases of pu lipoid nephrosis, it will, I think, be found th albuminuria may persist with a very high total da loss of albumin at a time when the œdema is rapic disappearing or almost absent, and if the theory blood depletion and lower osmotic pressure were t explanation of the œdema, this should not be so. W are, therefore, once more confronted with an impas and must face the fact that the albuminuria, which the one great index of a renal disturbance in cas of lipoid nephrosis, does not, on existing eviden explain the œdema in these cases.

Certain Phenomena of Diuresis.

We can obtain some further information releva to our problem by examining various methods which diuresis can be promoted in these cases. I once polyuria can be established the œdema su sides, and the mechanism by which polyuria can provoked should therefore throw indirect light on t mechanism by which the œdema is governed.

Of the diuretics which often act successfully "renal" œdema there are at least three groups, whi may be classed as follows: (*a*) urea and its precurso (*b*) alkalis; and (*c*) acid-producing salts. In t first group must probably be included the high prote diets, and I related how, in the case described, ur in large doses was responsible for a rapid diuresis a reduction in the œdema.

In sharp contrast to this method must be plac that in which alkalis are employed. No discussi of œdema can in any way be complete without so reference to the school of thought which holds th acidosis is an important, if not an invariable, featu of œdema. M. H. Fischer may be quoted as one the chief exponents of this view. His theory is large based on experiments on frogs, and with colloid substances such as gelatin. He believes that it essentially the swelling of the tissue colloids under t influence of acid which is the main source of œde in all cases. It would be impossible in the course a single lecture to discuss the interesting views this worker, which are frequently expressed in t vigorous language of an iconoclast. Fischer belie that alkalis are the essential basis for success treatment in practically all cases of œdema and nephritis, and very similar views, perhaps characteris by an equal enthusiasm, are to be found in the wo of Osman in this country.

The advocates of alkalis—and I may claim to numbered amongst them—have apparently nev been lacking in enthusiasm, for I have been interest recently to read a seventeenth century work Dr. William Coward, of this College, who was enraged by the presumption of certain authors w had dared to belaud the use of acids in medicine th he published a volume entitled "Alcali Vindicatum or, "The Acid Opiniator not guilty of Truth," which his enthusiasm for alkalis led him so far to cover with contempt a rival who had backed h favourable opinion of acids by the statement th "Seamen and Surgeons had been cured of the Scur be eating Oranges and Lemons in Spain," after th return. Ignorant both of the action of vitamins a of the effect of citrates on the reaction of the urin Dr. Coward in an outburst of sarcasm wrote, "I lo a Man who to make good his Cause tells half a Sto and draws an Argument from a Tarpaulin to uphe a main point in Physick."

Reverting to the use of alkalis in nephritis, must recognise that diuresis can frequently be induc by their use if the administration is pushed to sufficient degree. Osman gives as much as grs. 10 or grs. 2000 of alkali, in the form of potassium citra

otassium bicarbonate, sodium citrate, and sodium icarbonate to many of his cases, and in spite of ertain alarming accidents in the nature of tetany, appears that his method has not infrequently been uccessful in cases of mixed nephritis of desperate haracter. On the other hand, we must not ignore ne fact that diuresis in similarly desperate cases has ometimes been achieved by the use of calcium hloride. Blum and the Strasbourg school are chiefly esponsible for this work. When calcium excretion is ius promoted, the sodium content of the urine ncreases also, as shown by Keith, Barrier, and Whelan, ut the most interesting fact from the point of view f our immediate inquiry is that Salvesen and others ave established that such calcium administration ot only increases the urinary acidity but may actually use a severe acidosis. We are, therefore, faced ith the paradox that diuresis and improvement in the dema of nephritic cases can apparently be brought out either by substances which render the urine kaline, or by others which render the urine acid.

A possible explanation of this is afforded by the ork of Stieglitz, who by means of indicator dyes as brought forward evidence that the reaction of e actual cells of the kidney is always the opposite the reaction of the urine. And the same worker ntends that any measure which tends to change e normal titre of the renal blood will act as a imulus to the renal cells, and hence tend to produce uresis. We must further note that following the ork of Nash and Benedict there has been a tendency nongst biochemists to regard the breakdown of mino-acids into ammonia, which is one of the main otective mechanisms against excessive acidity of the od, as brought about by the agency of the kidney, d not, as was formerly believed, by the liver. It is ll too soon for any one to draw final conclusions m this mass of complicated observation, but it uld seem to point to the conclusion that the work of e kidney in cases of œdema is directed to compensa- g an existing derangement of the normal blood emistry, and though the strain of such compensa- n may damage the kidney the primary pathological ocess is an extra-renal one.

Experimental Œdema.

Turning now to the field of animal experiment. find a series of failures which in sum seems to to provide strong presumptive evidence against theory that œdema is the result of damage to kidneys. For as far as extirpation experiments concerned, no one has succeeded in producing ema by any operation on the kidney, and when we n to the various poisons which on intravenous ection cause a chemical nephritis, we find that with ingle exception none of them can produce œdema. e exception is uranium, and it appears that in mals poisoned by uranium a chemical nephritis l œdema can be produced if the water-intake is cibly increased simultaneously. I have seen it ted that the œdema of uranium poisoning occurs n when the animals' kidneys have previously been noved; but as I have failed to find corroboration the statement, I do not wish to stress it. I feel ot unfair, however, to point to the grossly artificial ure of these experiments, which must surely duce toxic effects on extra-renal tissues which y alone be sufficient to cause œdema, and that h is the case is the conclusion reached by many of se who have had most experience with this type experimental work. It is impossible to read criptions of these experiments, such as that to found in the monograph of Loeb, without being ressed by the dissimilarity between such experi- ntal œdema and that seen in pure lipoid nephrosis. l this work as a whole seems to me to support ner than challenge the belief that "renal" œdema of extra-renal origin. The same conclusion is ched if we examine the interesting experiments ntly devised by Aldrich and his associates, who e made prolonged study of the rate at which salt ition disappears after it has been injected into the skin of patients with various types of œdema. Without entering into details of their findings, it may be said that even in cases of so-called renal œdema they have found strong evidence of an abnormal avidity for water on the part of the tissues, both during and before the occurrence of the actual œdema.

Theories of Œdema.

Throughout this lecture I have made no attempt to explain the mechanisms by which the passage of fluid into the tissues, which we speak about as œdema, may be produced. No one, I think, who has given more than superficial attention to the enormous amount of work which has been done on this subject would presume to support any existing explanation of the facts with anything other than diffidence. Well-known treatises on the subject, such as the monograph by Loeb, or the work of Martin Fischer, tend to leave the reader in a state of confusion as great as that in which he may have begun his study of the subject, and we are, I think, forced to the conclusion that there is no theory of œdema before the medical world to-day which will explain all the known facts, but the theories which depend on the hypothesis that the œdema is a direct consequence of renal injury break down almost from the onset.

Elwyn, who must be quoted amongst those who have given particular attention to this subject, finds it impossible to do more than summarise existing facts, and put forward a tentative hypothesis to the effect that the œdema is a compensatory process. He believes that amongst the physiological constants of the body the blood volume is an important one —i.e., that in all circumstances, if life is to be maintained, the volume of the blood must remain constant. In cases of "renal" œdema, and of lipoid nephrosis as an outstanding example of such cases, he believes that reduction in urinary volume is the first compensatory mechanism to be brought into play and is directed to arrest the loss of albumin in the urine. From this he goes on to the belief that when this first great gateway of escape for the fluids from the circulation is partially closed, an increase in the blood volume would necessarily occur if some other gateway were not open. The only other avenue of escape for the fluid is into the tissues and thither it proceeds. This theory, as its author frankly says, is merely a statement of certain regulating mechanisms, and offers no explanation of the mechanisms by which the oliguria is produced or the transudation into the tissues brought about. Acceptance of it would seem to imply a change in the permeability of capillaries throughout the tissues, or, in other words, the existence of an extra-renal factor as a main factor in the production of so-called renal œdema.

General Conclusion.

I have now put before you the main reasons for my belief that *œdema in nephritis is at once suggestive of pathological change in tissues other than the kidney, and that such pathological change is not the result of nephritis, although it is more than probable that the renal and extra-renal damage have a common cause.* If this view is accepted, it seems to me to call for a fundamental change in our conception of the nature of nephritis, whenever that term is employed to describe a clinical association of œdema and albuminuria with or without hæmaturia, nitrogen retention, and cardiovascular changes. No one to-day would dream of regarding a case of acholuric jaundice, or of myelogenous leukæmia, as an example of splenic disease, and similarly I feel that the time has come when we must, at any rate in all cases where œdema is prominent, direct our attention first to the extra-renal tissues and search there for the factor that is the cause of pathological change of a very wide nature.

Lumleian Lectures
ON
EPILEPSY.

The Lumleian Lectures, 1928, delivered at the Royal College of Physicians of London

BY JAMES COLLIER, M.D. LOND.,
FELLOW AND COUNCILLOR OF THE COLLEGE; PHYSICIAN AND LECTURER ON MEDICINE, ST. GEORGE'S HOSPITAL.

LECTURE II.*

Delivered on March 27th, 1928.

THERE are several separately described diseases which have a close affinity with epilepsy; perhaps they are associated together clinically, or though not clinically associated the manifestations are very like or parallel to those of epilepsy; or they may arise under the same circumstances as does epilepsy. And the only successful treatment of some of them is that which is applicable to epilepsy. I submit that a metabolic dyscrasia is the causal factor of these several conditions, which are migraine, pyknolepsy, narcolepsy, vaso-vagal attacks, syncopal attacks, and tetany. Three of these are well known to occur, as does epilepsy, from local lesions of the brain, and these are migraine, narcolepsy, and tetany, and migraine is also met with in renal disease. There seem to be very good grounds for including these maladies in the same clinical and pathological group with epilepsy, of which some of them may be only varieties. I shall now put before you the relations between these maladies and epilepsy.

MIGRAINE.

Sometimes personal, but often hereditary and familial, this malady may appear in early childhood, or at any subsequent time, and tends to persist throughout life. The attacks are characteristically paroxysmal and often regularly periodic, and they often occur on waking in the morning, as if dependent upon some metabolic change which occurs more readily during sleep. In women they tend to cease during pregnancy. The occurrence of attacks of migraine in an epileptic person, though not ver common, is of profound interest and importanc The epileptic attack may alternate in regular perio with the attack of migraine. A patient, migraino during childhood, has lost the migraine at puber with the development of epilepsy, and vice vers Most remarkable of all are the cases first record by Gowers, in which epilepsy of many years' duratio ceased and was replaced by attacks of migrain which again lasted for many years and, with the disappearance, epileptic attacks again appeare In these cases it was as if the attacks of migraine an of epilepsy were interchangeable and that they we of a similar nature and due to a similar cause.

The symptoms of migraine may be usefully an justly divided into two strictly separate group because one of these groups so often appea without the other; indeed, in some patien the two groups never appear together, and others the symptomatology throughout life is co fined to one group only. The first group that of the hallucinations, paralyses, and ment states, and the second is that of the headache an vomiting. I maintain that a state of lowered blo pressure is always present with both groups. T symptoms of the first group almost exactly resemb the symptoms which occur in epilepsy, except in tw notable points. The one is that they are so tar in the onset and last for such a long time, in contr distinction to the flashing onset and short duration the epileptic attack. The other point is that t migrainous attack is never associated with convulsio The auras or hallucinations of migraine are the sam phenomena as those of epilepsy, but they last minut or even hours, instead of fractions of a second, an therefore admit of better analysis and descripti by the patient. They are most often visual an common sensory auras and only rarely of an auditor gustatory, or olfactory nature. The paralysis, aphas and mental states are in reality the same as in epileps but they last longer.

The symptoms of the second group have th correspondents in less degree in the headache, vomitin and vestibular disorientation which often follows t epileptic attack. In both migraine and epilepsy th seem to be the result of rapid increase of intracran pressure from actual swelling of the brain. migraine with headache there must be actual swelli of the brain to account for the headache and to accou for the remarkable paralysis of the individual ocu motor nerves, which only occurs in attacks in whi the headache has been unusually severe, and al for the sudden death which has been recorded in few cases during an attack of ophthalmople migraine. Recurring paralysis of the sixth ner with each successive severe headache, the paraly abating or disappearing in the interval betwe the attacks, can only be explained on a mechanic basis. The theory recently put forward that swelli of the pituitary body can account for the ophthalm plegia and some other phenomena in migraine in my opinion, unthinkable, because of the distan and highly protected position of the sixth ner On the other hand, increased supratentorial pressu from local swelling of the brain with pushing backwar of the brain stem and stretching and pressure up the sixth nerve at the foramen tentorii is an acceptal explanation, for it is in this way that sixth ner palsy is so commonly caused in cases of cereb tumour. Spitzer showed, in a series of autops upon subjects who had long suffered from migrai that dilatation of the lateral ventricle upon one si was a constant feature, and he attributed migrai to intermittent occlusion of the foramen of Mur by a ball-valve action of a turgid choroid plex It seems to me more probable that swelling of c hemisphere from time to time would be quite lik to cause unilateral distension of the ventricle, ju as a cerebral tumour often does. There is so evidence that actual swelling of the brain does oc in migraine with headache. I have already refer in my last lecture to a theory of epilepsy based up

anaphylactic reaction within the brain. I have a considerable number of cases in my records in which such conditions as asthma, paroxysmal swelling of the tongue, angio-neurotic œdema of other parts of the body, and urticaria occurred in patients with migraine, and this suggests the possibility that a local anaphylactic reaction within the brain, giving rise to local œdema and swelling, may be the cause of the headache in migraine and in epilepsy. It seems quite clear that the two groups of symptoms in migraine result from two distinct processes. The first group of epilepsy-like symptoms must result from some process which is nearly identical with that occurring in epilepsy; the second group of the headache and vomiting must result from local swelling of the brain. The two processes may coincide, producing the fully symptomatic attack of migraine. Much more commonly the second process occurs alone, so that migraine is best defined as paroxysmal headache. Often the two processes occur in the same patient, but never at the same time—the visual phenomena and the headaches constitute separate attacks. Sometimes the first group of symptoms is the sole manifestations of migraine throughout life.

A further close relation between migraine and epilepsy is that either condition may result from an organic lesion of the occipital lobe and that the visual hallucinations so occurring may be identical in character, and also that both conditions may arise in the course of renal disease. I have seen one excellent example of migraine from a lesion of the occipital lobe.

A middle-aged woman was admitted under my care into St. George's Hospital, her doctor having sent her to me as a case of cerebral tumour. She had a story of very typical migraine of three years' duration. I could find no sign whatever of any intracranial tumour, but we observed on several occasions very characteristic attacks of migraine with teichopsia and hemianopia. She was treated for migraine and the attacks ceased and did not recur during a peroid of about a year that she was under my observation. Some eighteen months later she became insane and was admitted to a mental hospital, where in a few months she died. Her doctor, who had never been satisfied with the turning down of his diagnosis of cerebral tumour, saw to it that an autopsy should be held, and thereafter took care that the pathological findings should be properly rubbed into me, for in the outer and under part of the occipital lobe corresponding to the original migrainous symptoms a cerebral tumour was indeed found.

Lastly, there are those rare cases, several of which are recorded by Gowers, in which the attacks seemed to be a blend of migraine and epilepsy or, alternatively, to be attacks of migraine in which severe convulsion occurred.

I submit that migraine may be considered as a protracted form of local epilepsy, having its seat of origin most often, but not always, in the posterior regions of the brain and having the especial association of swelling of the brain which gives rise to the conspicuous headache and vomiting. Migraine is usually regarded at the present day as dependent upon a metabolic dyscrasia, and its close similarities and relations with epilepsy are of some weight in the hypothesis that epilepsy has a similar origin.

NARCOLEPSY.

This remarkable condition was first noted by Westphal in 1877, and by Fischer in the following year, and was considered by them to be an unusual form of epilepsy. But Gelineau, in 1880, applied the name narcolepsy to his description of further cases, and considered that the condition was quite distinct from epilepsy. In English-speaking countries narcolepsy has been confused with all of the many conditions in which undue sleepiness and sleepy attacks occur, but in Germany this symptom-complex has been well recognised since Westphal first described it. An admirable monograph has recently appeared in *Brain* by Dr. Adie. This condition seems to persist with slight variations of intensity throughout life. It is more common in males. It seems to be personal and not hereditary, and the subjects present for the most a normal physical and mental make-up, but sometimes, as in epilepsy, there is mental deficiency, and there may be bodily peculiarities which have suggested endocrine deficiency.

Two quite different kinds of attack occur in nearly all the cases of narcolepsy. The one is the sudden onset of apparently normal sleep, which comes, usually at a moment of inattention, several times a day. The sleep lasts from a few seconds to a few minutes, it is rousable, and the patient is wide awake at once and knows that he has slept and sometimes he has dreamed and can describe the dream. Many patients have a warning of the attack in the way of a feeling of intense fatigue or a cephalic sensation and, thereafter, can so far repel the onset of the attack by an effort of will as to be able to sit down or get out of harm's way. But the attack is inevitable, however long it may be resisted, and is always the more severe the longer it is resisted. Some patients have headache after the attack. On occasion, however, the attacks may occur suddenly and without warning when attention is concentrated and in midst of action, and they were noticed under war conditions, during bombardments, and on listening-post duty, where the penalty for sleeping is death.

Instantaneous onsets of sleep in the midst of action are well-known phenomena in those who have been deprived of sleep for very long periods, and may be deemed almost normal phenomena under such circumstances when bodily metabolism must be seriously disturbed by the prolonged breaking of a fundamental physiological succession in life.

The second variety of attack is termed by Dr. Adie the "cataplectic" attack. It seems to be produced mostly from a sudden emotion, and this emotion may be of any kind, but it is most often a pleasurable emotion, and the most potent emotion is that which accompanies bursting into laughter. There is a sudden feeling of intense weakness in the limbs, which go flaccid. The patient drops anything that he may be holding and crumples to the ground, but often only into the sitting position. The eyelids drop and the head falls forward with the jaw dropped. There is complete inability to move and generally inability to speak, but consciousness is completely retained, so that the patient is able afterwards to recount every event and repeat every word spoken during the attack. Grimacing and protrusion of the tongue sometimes occur, as if there were some sort of facial spasm, and curious movements of the head may be seen, as if the patient were making partially successful attempts to keep his head upright and then failing; or similarly with the limbs. These movements have been regarded by some as convulsive movements, but from the clear description by one of Dr. Adie's patients, they were in his case due to repeated efforts to overcome an increasing weakness. The attacks last but a few moments or, at their longest, a few minutes, and recovery is almost abrupt. Often the patient has time to sit down or get to safety. Dr. Adie has shown very conclusively that in narcolepsy there is no fundamental distinction between the two varieties of attack. For the sudden attacks of sleep, usually without cause, may occur upon any emotion and the cataplectic attacks may occur spontaneously, and blends are met with in which cataplexy and sleep occur together.

In this connexion it is interesting to consider that hearty laughter is in all acceptation a "fit" of reflex origin, maintained by an impulse so strong as to often defy the control of the will. It completely interrupts the train of mental activity; and the hearty laugher collapses temporarily incapacitated from mental and bodily activity. In so many languages, too, there is an expression equivalent to our English, "to die of laughter," "to be paralysed by fear," and "to be speechless with rage." It would appear therefore that both the attacks of falling asleep and the cataplectic attacks of narcolepsy have their basis in a normal event, for we all fall asleep, and those of us who are risable may "die

of laughter," and that in narcolepsy we are not dealing with any qualitative change in the reaction of the human being to its surroundings, but rather with an exaggeration of and misplacement of events, that occur in the state we call normal. Following upon the brilliant researches of Pavlov upon the conditioned reflexes which prove clearly that sleep and internal inhibition are identical phenomena, Dr. Adie further correlates the tone-loss attacks and the sleep attacks of narcolepsy as phenomena of inhibition. He considers that this malady is a functional disorder of the nervous system, and that it is primarily a disorder of an endocrine nervous system made up of the nucleus hypophyseus and adjacent centres of the between-brain, and laying great emphasis upon the highly correct general principle that every expression of disordered cerebral activity from functional disturbance has a corresponding equivalent resulting from local organic disease of the brain, he proceeds to detail one case of his own and another recorded by Stiefler, in which true narcolepsy resulted practically as an isolated phenomenon from local organic disease of the brain, presumably in the subthalamic region.

In this short description of narcolepsy you will be struck by the parallelism between many of its signs and those of epilepsy, and by the fact that authority has advanced a metabolic disorder peculiar to the individual and, alternatively, a local lesion of the nervous system, and collectively, therefore, both of these conditions as the pathological explanation of the malady. And this is the same pathology which I am submitting to you as the explanation of epilepsy.

In Dr. Adie's monograph one is impressed by his contention for "true" narcolepsy, I presume in contradistinction to "false" narcolepsy, and I suspect that the latter collection would include those cases of narcolepsy which were in danger of showing epileptic phenomena. I cannot help feeling that there has been a little picking and choosing of the cases, and while I am sure, from my own observations, of the correctness of the clinical picture which he and others have drawn, and while I fully realise the immense value of the succinct and exact description of narcolepsy laid down by him in teaching the medical world how to recognise this malady, yet surely I have seen cases in which narcolepsy and epilepsy were conjoined, and I think that the observers of old time, from Westphal and Fischer onwards, were not all wrong when they classed some of the cases as epileptics. The arguments against the relation with epilepsy are not very strong. That it has no familial relation is met by the fact that epilepsy itself is so often a personal as opposed to a familial disease. That it does not occur before puberty agrees with the well-known class of the epilepsies which appear at puberty. That there is no convulsion in narcolepsy does not convince, for pyknolepsy was described as being without convulsion, and that is certainly an epilepsy proper. Moreover, the grimacing and protrusion of the tongue have not been either precisely described or explained by those who deny spasm in narcolepsy. When Adie states his determination that narcolepsy and epilepsy are not the same, because in narcolepsy some of the attacks are reactive, whereas in epilepsy the attacks are never reactive, I frankly object that it has been laid by great authorities, including Sir William Gowers, that the most frequent of all the tangible excitants of the epileptic fit is fright, and that I have seen many examples of this, such for instance as a lad who was a compositor's apprentice, who one day standing at work before his case, suddenly saw a train of great rats run from behind it across his bench. He threw his first fit there and then, and that same day, in my presence at the National Hospital, had two other severe and typical general attacks of epilepsy. Moreover, I do not see why the multitudinous records of reflex epilepsy from almost every possible form of stimulus, both psychic, special sensory, and sensory, and occurring indiscriminately in idiopathic epilepsy, organic epilepsy, and symptomatic epilepsy should be excluded from the class of attacks which are called "reactive."

It would seem, therefore, that narcolepsy is usually a malady per se, but that it is closely parallel with epilepsy in its mainfestations, and that it has a similar pathology in a metabolic dyscrasia and in local lesions of the nervous system, but that in some cases the nature of the metabolic change is such as to produce a coincidence of the two diseases in the same patient.

PYKNOLEPSY.

Friedmann, in 1906, separated from among the various forms of epilepsy a type which he deemed worthy of separate description. It was characterised by the somewhat fulminant onset in childhood of attacks indistinguishable from the minor attacks of epilepsy, which becoming very frequent and sometimes innumerable, persisted for years with an unvarying monotony of character, but were associated with no ill-health and with no impairment of mental or physical development. They were utterly uninfluenced by treatment and invariably came to a spontaneous end some time after puberty, never again to occur. Heilbronner and Stier confirmed his observations and named the condition "pyknolepsy" from the characteristic frequency of the attacks, and wished to separate the condition as entirely apart from epilepsy and a malady sui generis, and Dr. Adie has recently published an excellent monograph upon the subject. The attack in pyknolepsy is said to be always an inhibition of the higher psychical processes lasting from five to ten seconds; the power of speech and of voluntary movement is in abeyance, but the automatic movements are retained; the patient stands with the limbs relaxed, staring vacantly, but he never falls and never drops anything that he is holding; the lids may flicker, the eyeballs may roll upwards, but there are no convulsive movements and consciousness is never entirely lost. I have seen many cases of pyknolepsy which corresponded exactly to the type of Friedmann and Adie. I have seen many others which corresponded, except that each presented some feature which betrayed the presence of epilepsy. Thus I had one case whose sister had major epileptic attacks, another very typical in every way, but that he had had four severe general epileptic attacks; another who always fell in his attacks and, again, one who always had convulsion of the face and upper limbs. Yet these were all cases in which the attacks were multitudinous, in which high intelligence was preserved, which were rebellious to treatment, and which came to a spontaneous and permanent cure somewhere about the age of 20 years. One of my patients had to be removed from public school on account of the disturbance his innumerable attacks caused and was under my care at the National Hospital. During the period of his most frequent fits he matriculated and graduated as a Bachelor of Science. He has now had no attacks for years and is a master at a public school. Any physician who sees many cases of epilepsy will be able to pick out some which answer exactly to the description of pyknolepsy, but the number of cases which just fail to correspond because they show some typical feature which brands them as cases of epilepsy are so many that the contention that pyknolepsy is a disease sui generis and, apart from epilepsy, falls to the ground utterly. It is, in fact, simply a variety of epilepsy. I take it that variation in the nature of the metabolic disturbance which underlies epilepsy is responsible for type and the constancy of the phenomena which result. This description of pyknolepsy has, however, been very useful, for it has pointed out to the medical world that in epilepsy provided that high intelligence be maintained and education be uninterrupted, though the attacks be very numerous over many years and though treatment be entirely futile, there is good hope of complete and lasting recovery.

Vaso-vagal Attacks.

These curious attacks which make up a very definite syndrome and which have an important bearing upon epilepsy and conditions related to epilepsy, were first written about by Bonnier in his treatise on Vertigo under the term "syndromes nedullaire." Gowers was, I know, well conversant with the condition for many years before he published a lecture in THE LANCET in 1907, entitled Vagal and Vaso-vagal Attacks. This work does not seem to me to have received the attention in medical literature that its truth and importance merits.

The attacks were called vagal attacks because of the common occurrence of epigastric sensations of discomfort, of cardiac discomfort, and of respiratory constriction sometimes associated with an all-pervading impression of impending death, comparable to a mild degree of that which occurs in angina pectoris. They were called vasal because of the conspicuous pallor of the surface and coldness of the extremities. For these same reasons Bonnier called them "medullary syndromes." Gowers placed them on the borderland of epilepsy because some of his patients who had vaso-vagal attacks were frank epileptics and because of the change of mental state and semi-conscious condition during the attack. He placed them also close to migraine, as some of the patients also had migrainous attacks and because of the slow lasting aura, the prolonged symptoms, and the conspicuous surface pallor. He said: "If we can conceive a minor epileptic attack that is extended, its elements protracted so that the aura, the pallor, and the semi-consciousness last minutes or hours instead of fractions of a second, its features would be so different that its nature would not be suspected. Velocity is an essential element in the attack of ordinary epilepsy, but it does not preclude the possibility of deliberation in attacks not far removed from epilepsy." Gowers attributed the ashen pallor and the cold extremities to general vaso-constriction, as was fashionable in the pathology of his time, but I am convinced, as the result of many observations, that the pallor at the commencement of the epileptic attack and that seen in the vaso-vagal attack, the attack of migraine, and in the syncopal attack, are all due to the same cause, and that is a general fall in blood pressure. In the vaso-vagal attack one has plenty of time to accurately determine this fall of blood pressure.

I have seen many patients with vaso-vagal attacks, and in one of these I have observed the details of the attack from start to finish on at least 20 occasions. These have been so interesting and so highly important in connexion with my subject as to warrant my describing them to you in detail.

The patient is a lady of strenuous life and of athletic habits, with no family history of epilepsy or of migraine, but she has three times in her life fainted and fallen like a stone—once in childhood at the sight of an accident, once on the receipt of unexpected bad news, and once on being shown at her own request a pathological specimen in which she was greatly interested. The attacks never occur when she is feeling thoroughly well, but there is always a premonitory state of bodily ill-feeling and negative emotional tone. They begin abruptly with a general feeling of weakness of the limbs, soon followed by a general impairment of consciousness, which she calls a "stupid head," in which she cannot concentrate nor be very direct in her speech, and in which she is restless to the extent that she seems unable to sit or lie down, by which she means she knows well that the attack may be mitigated or aborted. She can, by a strenuous effort, delay the development of the attack so that she can get home or into a shop when walking in the street, but such delay seems always to increase the severity of the attack. The skin becomes increasingly pale and ashen and the extremities become very cold. Then there is a feeling of restriction of respiration referred to the lower chest. It is never painful nor associated with any fear of death, but the patient will clutch at the lower chest and say that she has difficulty of breathing, but there is no dyspnœa. At this stage the blood pressure falls further and somewhat rapidly, but there is no increase in the pulse-rate, which is somewhat remarkable. Hearing becomes increasingly distant and vision pales, and consciousness is lost somewhat suddenly and so completely that this patient has fallen downstairs with considerable bruising without any after memory or with the sole residuum that she heard herself fall but felt nothing. Consciousness is usually lost for a few seconds only, but in severe attacks it may be lost for as long as a minute, and in this case there is always convulsion. It is of a clonic type and commences, and is most conspicuous, in the face, and spreads thence to the neck and arms, but never to the trunk or legs. It lasts a few seconds. Consciousness is regained slowly and this is never followed by sleep. There is no enuresis. There is no consequent headache, but the patient is somewhat knocked out and has a stupid head and complete anorexia for the rest of the day. There is much coldness and shivering as the attacks pass off. These attacks may abort and the symptoms may cease at any stage of their development. The shortest will last a quarter of an hour and, in the longer attacks, it may be from an hour to several hours before consciousness is lost. They commenced about the age of 22 years and were numerous between the ages of 25 and 30 years, two having occurred in one day and often several a week. Now, in later life, they are very rare and occur only at intervals of years.

This story shows a good example of the vaso-vagal attack, but it is specially important in demonstrating the occurrence of convulsion in many of the attacks which did not occur in Gowers's cases, and this convulsion brings the condition very near to epilepsy. The picture of this case will at once bring forcibly to your minds Gowers's simile of a very long-drawn-out minor attack. There is also a very close resemblance between such attacks and migrainous attacks. For if you take away the headache and the vomiting and the visual symptoms from a severe attack of migraine, you will leave the low blood pressure, the ashen countenance, the bodily coldness, the mental and physical disability, and the absolute anorexia which characterise many vaso-vagal attacks.

When the patient I have just described to you was nearing the deeper stages of a severe attack, someone came into the room who had considerable experience of epilepsy, and he witnessed the convulsion and slow return to consciousness, and he told me forcibly that I was deceiving myself in not calling such an attack frank epilepsy because the patient was a close relative of my own. But I know that vaso-vagal attacks are not epileptic attacks, though like the attacks of migraine and narcolepsy, they may mix clinically with epilepsy and are amenable to the same medicinal treatment, and we shall do well to follow Gowers and to class them as distinct but belonging to the same clinical and the same pathological group.

Syncopal Attacks.

I have often thought deeply why fainting attacks have been so stringently separated as having no relation with epilepsy, and I suppose it is because the lowering of blood pressure is slow enough and prolonged enough to be so obvious, and because the syncopal attack so often appears as an affective reaction to some very definite though often trivial cause. When one considers the distinction which authoritative writers have made between epileptic and syncopal attacks, one finds the argument strained and hard to accept and the distinctions neither absolute nor applicable to many of the cases. I hold very strongly that the syncopal attack is not an epileptic attack, but I am convinced that it is a phenomenon of the same order and dependent upon a similar pathology and that it should be classified in the same group with epilepsy, migraine, narcolepsy, and vaso-vagal attacks.

The syncopal attack has a smaller incidence upon the population than has epilepsy, and in those who suffer, syncopal attacks are for the most much more rare events than are epileptic attacks in epileptic persons. They are usually personal, but they may be familial and hereditary. They do not commonly commence in childhood, but often more after puberty and, like the attacks of epilepsy and of migraine, they tend to persist during the whole of life, but to become rare as age becomes advanced. The onset may be quite sudden and the return to consciousness rapid; more often the onset is slow with obvious signs and symptoms of the lowering blood pressure before consciousness is lost and consciousness returns through a period of dazedness. As I have myself

witnessed the instantaneous attack and the slow attack occur in the same patient, confusion with minor epilepsy is here unlikely. Surely, whether the attack is rapid and very short, or whether it is slow and longer, will depend upon how rapidly the blood pressure falls and how quickly it regains the normal. As this rate of onset and recovery is one of the few actual points in the attack which are held to distinguish epileptic from syncopal attacks, the impossibility in thus separating the two conditions becomes apparent. Another point is that the syncopal attack is so often an affection reaction from a mental impression, from fear or horror, from the sight of blood, or from a stuffy atmosphere, but sometimes the syncopal attack has no tangible cause whatever and, further, the epileptic attack may be an affective reaction, the narcoleptic attack is usually so, and the migrainous and vaso-vagal attacks may, on occasion, be thus produced. This distinction, therefore, will not serve, and one has to make a diagnosis rather from the course of the case than from the nature of the attack. What has never been explained is why in some persons, who are otherwise healthy and normal, should there be this tendency to sudden fall of blood pressure with loss of consciousness, either spontaneously or as an affective reaction from causes which are utterly ineffective in producing like phenomena in the majority of the community. I submit that those otherwise healthy people who are subject to syncopal attacks have a personal metabolic peculiarity not far removed from that which I have suggested to you may be the underlying factor in epilepsy, narcolepsy, vaso-vagal attacks, and migraine. I submit that the fall of blood pressure so conspicuous in the syncopal attack is an essential element in all the others, and this, with the clinical similarities between these maladies, binds them together into one group.

Convulsion in Syncopal Attacks.

I wish now to draw your attention to the occurrence of convulsion in syncopal attacks. It is much more common than is usually allowed. Kussmaul and Tenner first proved that anæmia of the brain from any cause, including lowering of the blood pressure, might result in general convulsion. Forensic medicine experts have always allowed convulsion in syncopal attacks. Physicians have usually dismissed convulsion in their description of syncopal attacks with the remark that there may be a few twitchings of the muscles of the face, and have made the occurrence of distinct convulsion the standard of separation between the syncopal and the epileptic attack. Dr. Sutherland has recently said very definitely that whenever the blood pressure drops suddenly to below a certain point there must be convulsion. He was referring to the explanation of convulsion as it occurs in the Stokes-Adams syndrome and in paroxysmal tachycardia, and he dismisses such convulsion as having no connexion with epilepsy, but as the simple effect of dropping of the blood pressure, and he denies any justification of the term "cardiac epilepsy." He does not, however, account for the fact that only a few of the cases of heart-block, even with very long asystolic periods, have convulsions, and that this phenomenon is rare even with the most severe cases of paroxysmal tachycardia. Further, in cases of heart-block, I have seen frequently recurring minor attacks which were characteristically epileptic and which had never occurred before the heart-block developed. I have seen also local attacks and the usual convulsive attacks confined to face and upper extremities, and slow-drawn-out attacks like vaso-vagal attacks and severe general convulsions, and therefore I submit that there is a second metabolic epileptic factor which determines the occurrence of epileptic manifestations in these cardiac cases.

Alcohol Puncture and Syncopal Attacks.

In the performance of alcohol puncture for the relief of neuralgia, peripheral facial spasm, and painful periosteal points I have on at least 20 occasions observed syncopal attacks, and in every case these were associated with convulsion, commencing with deviation of the eyes and a gurgling sound in the throat and followed by facial clonic spasm, often spreading to the arms and sometimes becoming general and occasionally severe. The attacks commenced with the usual facial pallor and nausea and complaint on the part of the patient that he felt faint, the convulsion lasted perhaps half a minute and recovery was rapid and complete. All the patients were men who seemed otherwise healthy. The attacks seemed to have no relation to the pain or discomfort of the procedure nor to the amount of local anæsthetic or of alcohol used; indeed, I have seen them most often in injections upon the facial nerve, where the amount of either used would be less than five minims. Curiously enough, I have never seen a syncopal attack to occur in cases where a successful puncture into the Gasserian ganglion has been made and where both the pain and the shock effect might be deemed to have been greatest. Another physician, who has great experience of alcohol injections, tells me that he has observed similar syncopal attacks with convulsions in needling operations where no local anæsthetic nor alcohol have been used, as for, in example, in lumbar and cervical puncture.

These attacks which I have just described were obvious syncopal attacks and they were associated with convulsion in no way distinguishable from that of the epileptic attack. They occurred in a very small percentage of the subjects operated upon, and I submit that their occurrence was determined by a personal metabolic condition of the patient at the time which is not far removed from the underlying cause of epilepsy.

TETANY.

The association of epileptic manifestations with those of tetany, though they may be rare, are of importance in the argument that epilepsy has its origin in a metabolic dyscrasia, for tetany is provedly the result of metabolic disturbance, for it can be produced by calcium deprivation and by parathyroid extirpation, and removed thereafter by calcium administration and by parathyroid feeding. In rare instances it may appear as the result of a local lesion of the brain, and there are a few cases recorded in which both epilepsy and tetany resulted from a local lesion of the brain. Tetany has been often associated with the convulsions of childhood. In the clinical descriptions of tetany in its severe form Gowers calls attention to the occurrence of general convulsions of an epileptic order, and von Fraenkel Hochwart fully confirms this. Further, Gowers records the occurrence of tetany in association with vaso-vagal attacks. On the other hand, it is well known that the sudden onset of general tetany is usually associated with sudden loss of consciousness, as is the general epileptic attack. I wish to put before you two cases which will serve to illustrate this subject.

A woman well past middle age was admitted under my care at the Queen-square Hospital as an epileptic, on the grounds that she had for three years suffered from attacks in which she lost consciousness and fell and was generally convulsed, and thereafter experienced great pain and stiffness in her limbs. Immediately after admission she had an attack which was typical tetany in the four limbs, and it was discovered that a very complete thyroidectomy had been performed rather more than three years previously. She presented no symptoms of myxœdema. She had no general convulsion in hospital, but in one severe attack of tetany consciousness seemed to be greatly impaired or even lost. This case recovered rapidly upon calcium and parathyroid treatment.

A middle-aged woman came to my out-patient department at Queen-square with all the signs of tetany well marked, but with no obvious cause for these. I was busy for some time demonstrating so instructive a case to my class and admitted the patient into hospital without examining the retinæ. I was informed later in the afternoon that she had intense papillœdema. We were unable for some time to make any localisation for the tumour, but later slight nerve deafness appeared on one side, and the patient's condition

being urgent, a lateral recess tumour attached to the auditory nerve was exposed and removed. We were much troubled with the non-subsidence of the papillœdema and the other symptoms for a while, and by mental aberration, but these were obviously due to a hydrocephalic cystation from tissue dislocation, which righted eventually with a complete recovery of sight of mentality and of the tetany.

I hope that I have in some degree attained my object in bringing before you in this lecture a real relation, both clinical and pathological, between epilepsy and these several other diseases.

RHEUMATISM, TONSILS, AND GLANDS.

AN INQUIRY INTO THE RELATION OF TONSILS AND ENLARGED GLANDS TO CARDIAC DISEASE IN RHEUMATIC CHILDREN.

BY K. DOUGLAS WILKINSON, O.B.E., M.D. BIRM., M.R.C.P. LOND.,

PHYSICIAN TO THE BIRMINGHAM AND MIDLAND FREE HOSPITAL FOR SICK CHILDREN;

AND

A. G. OGILVIE, M.B., B.S. DURH.,

HOUSE PHYSICIAN TO THE HOSPITAL.

DURING recent years many papers have been published on the subject of rheumatism, and many writers have produced statistics in an attempt to assess the importance and results of removal of the tonsils. Some of the figures seem to suggest that the tonsil is of small importance, and its removal of no great use; others suggest the contrary. It was because of this apparent uncertainty that we have tried to follow up cases of chorea and rheumatism during a period of six years, to re-examine them, and to produce figures showing the relationship between the tonsil and cardiac disease in rheumatic children. The cases under consideration were all children under the age of 12 years admitted to the wards of the Children's Hospital, Birmingham, under one of us (K. D. W.) between Jan. 1st, 1921, and Jan. 1st, 1927. All the in-patient cases of rheumatism and chorea are included, and of necessity these comprise the more severe types seen during this period, because, owing to lack of beds, only children whose symptoms are urgent gain admittance to the hospital. The death-rate in the series under consideration reflects the severity of the infection. Approximately half the children had their tonsils removed while in hospital.

Out of a total of 153 cases, 15 died in hospital, leaving 138 whom we attempted to follow up; and of these, 71 were re-examined and 9 were found to have died since discharge from hospital. Among the remainder (58), classified as untraced, there were several children who are known to be in convalescent homes or institutions, where they could not be re-examined; these have been excluded from our figures.

The traced cases have been divided into three groups:—

1. *Normal*, which includes only cases who show no evidence of any cardiac abnormality or disability.

2. *Damaged*, including cases showing some evidence of cardiac abnormality, such as slight or doubtful enlargement, extrasystoles, or a systolic apical murmur without any definite evidence of valvular or myocardial disease. A number of cases in this group showed only a persistent tachycardia.

3. *Cardiacs*, comprising all cases with definite enlargement or valvular disease, and all cases with myocardial damage. Several of this group have no symptoms and state that they enjoy normal good health.

In this paper the state of the heart has been taken as a measure of the damage wrought by rheumatism, partly because it was considered the most definite and reliable index, and partly because alternative details such as height, weight, and general health would be liable to grave inaccuracy unless checked by comparison with a similar number of normal children drawn from the same population. This method of control proved impracticable. It was found impossible to indicate accurately either the severity of the original disease, or the degree of recovery. Children who, on admission to hospital, had such extremely severe pancarditis that they seemed almost certain to succumb to heart failure, have made good recoveries and lead active lives, while, on the other hand, some who did not seem likely to become victims of permanent cardiac disease have since developed organic lesions.

TABLE I.

Traced cases: males, 26; females, 54 = 80.

Original disease	Chorea, 28.	Rheumatism, 52.
Present state.	Number and percentage.	Number and Percentage.
Heart normal	15 (53·5)	12 (23·07)
,, damaged	10 (35·7)	10 (19·2)
Cardiacs	3 (10·8)	21 (40·38)
Dead	0	9 (17·35)

Table I. shows that chorea is very definitely less likely to be followed by cardiac disease than is frank rheumatism. This accords with common experience. It also shows the large number of girls affected, and demonstrates that rheumatism in its severe form is nearly twice as common as severe chorea. Those children who had both chorea and rheumatism have been placed in the rheumatic group.

Beneficial Effects of Tonsillectomy.

It is our present practice to regard all tonsils as suspicious foci of infection in rheumatism, and to view enlargement of the glands at the angle of the jaw as a definite sign of infection of the lymphatic system via the tonsils, and as an absolute indication for their early removal whatever their size or appearance. During the period under review, however, enlarged tonsils only were removed.

At first the operation was approached with some misgiving because it was feared that such a disturbance might upset the patient severely; but experience proved reassuring, and suggested that the operation might be performed early with beneficial results, so that it is now our practice to remove tonsils as early as possible, even in the presence of acute chorea or with symptoms of severe rheumatic infection, provided that signs of heart failure are absent. This practice seems to be justified by results, for it is unusual to find any disturbance, and exceptional to be able to tell the day of operation from inspection of the temperature chart, while the patients often show a definite improvement in symptoms, appetite, and condition soon after.

Tonsillectomy was done in 35 cases of the above series, in 9 children with chorea and 26 with rheumatism. Thus, the more severe cases were more frequently operated upon.

TABLE II.

Present state.	Tonsillectomy: 35 cases.		Non-tonsillectomy: 45 cases.	
	Number and percentage.		Number and percentage.	
Heart normal	15 (42·8)		12 (26·7)	
,, damaged	8 (22·8)	48·5	12 (26·7)	60
Cardiacs	9 (25·7)		15 (33·3)	
Dead	3 (8·7)		6 (13·3)	

Table II. seems to show quite definitely the beneficial effect of the removal of the tonsils, for although the operation was performed more often in the rheumatic group—the severe infection which tends to damage some 60 per cent.—yet the cases operated upon show a decidedly smaller incidence of cardiac disease than the unoperated. The higher death-rate in the unoperated cases must, to a certain extent,

be discounted as being due in part to the fact that some children were admitted to hospital far too ill for any operative proceeding, and died without improving. In order to reach any conclusion as to the ultimate results of tonsillectomy, the deaths should be discarded and only the 71 cases re-examined should be considered.

Table III. shows the cases rearranged in two main groups—32 cases without tonsils contrasted with 39 cases with tonsils—and in further sub-groups to bring out the effect of the presence of enlarged glands.

TABLE III.

Present heart condition ..	Normal.	Damaged.	Cardiac.	Totals.
Present throat condition—				
Tonsils but no glands ..	5	2	2	9
,, and glands ..	6	9	15	30
Glands but no tonsils ..	1	2	1	4
No tonsils, no glands ..	15	7	6	28
Totals	27	20	24	71

It can thus be seen that of operated cases only 4 out of 28, or 14·3 per cent., show enlargement of the glands at the angle of the jaw, while 30 out of 39, or 71·7 per cent. of the unoperated cases show enlargement. The significance of the figures is emphasised when the results are shown as percentages, as in Tables IV. and V.

TABLE IV.—*Rheumatic Children.*

Heart condition.	Healthy throats.	Tonsils and glands.
	Number and percentage.	Number and percentage.
Normal (27 cases) ..	20 (74)	6 (20)
Damaged (20 cases) ..	9 (45)	9 (45)
Diseased (24 cases) ..	8 (33)	15 (62·5)

TABLE V.

Throat condition.	Normal hearts.	Damaged hearts.	Diseased hearts.
	Number and percentage.	Number and percentage.	Number and percentage.
Normal (37 cases) ..	20 (54)	9 (24·3)	8 (21·7)
Tonsils and glands enlarged (30 cases)	6 (20)	9 (30)	15 (50)

It may be urged that the numbers under consideration are too small to allow of any definite conclusion, but the results of the analysis of the figures in the table are so striking that it seems difficult to avoid the inference that the tonsils, and especially tonsils associated with enlarged glands at the angle of the jaw, have an important bearing in rheumatic infection.

There are two further considerations which suggest that the glandular enlargement is of some importance in children and young people. While chronic tonsillar infection in them is very frequently accompanied by enlarged glands, this association is relatively seldom seen in adults. Further, in children who die of acute rheumatic heart disease the enlargement of bronchial and mediastinal glands is always a marked feature of the post-mortem findings. The glands are not very big, but all of them are somewhat enlarged, so that they are far more obvious than in children who have died of other conditions.

The children who form the subject of this communication were treated, as far as was possible, uniformly. Prolonged rest was considered of first importance, the child being kept flat in bed with only a low pillow, and as quiet as possible. At first all children were fed by a nurse, and allowed to make no unnecessary effort. Salicylates were given during fever and when any articular signs were present, but cod-liver oil is thought to be more useful when the temperature has settled down. The diet was in all cases confined to milk, milk foods, and jellies at first; a simple, well-prepared, varied diet being allowed later. Sunlight, open air, and good general conditions were found to be important factors, but the children who did best were those with devoted mothers, not necessarily in the best circumstances, who conscientiously carried out the directions for treatment after the child left hospital. The return to activity was gradual and was controlled by observation of the pulse-rate before and after any effort. The average stay in hospital was slightly over three months, but many children spent long periods in convalescent homes in addition, and the total period of rest probably averaged over six months.

Conclusions.

1. Chronic infection of the tonsils is commonly associated with rheumatism and chorea in children, and frequently causes enlargement of the glands at the angle of the jaw.

2. Children who have rheumatism are less likely to develop organic cardiac disease if the tonsils are completely removed.

3. In such children tonsillectomy results in the disappearance of the enlarged glands in over 70 per cent. of cases.

4. While the enlargement of the glands may be taken as an absolute indication for the removal of the tonsils in rheumatic children, it is probable that, in order to obtain the best possible cardiac results, tonsillectomy ought to be performed before the glands become enlarged.

SIGNS BY WHICH TO DIAGNOSE CONGENITAL DISLOCATION OF THE HIP.

BY GEORGE PERKINS, *M.C.*, M.CH. OXF., F.R.C.S. ENG.,

ASSISTANT SURGEON, ROYAL NATIONAL ORTHOPÆDIC HOSPITAL; ORTHOPÆDIC REGISTRAR, ST. THOMAS'S HOSPITAL.

THE treatment of congenital dislocation of the hip-joint results in a complete cure if reduction is made early enough. If treatment is commenced before the age of 3 the percentage of cures reaches 75, and every additional month after that age diminishes the likelihood of a perfect result. In the older patient it is not so much the difficulty of reduction that impairs the result as the secondary changes in the acetabulum and the head of the femur, which conduce to chronic arthritis and premature old age of the joint. That early reduction is essential is well known, and yet few patients with congenital dislocation of tne hip reach hospital before the age of 3, and very few of these are sent up with the correct diagnosis. The majority of them have been examined at some time or other by their family physician, who has failed to diagnose the presence of a dislocated hip.

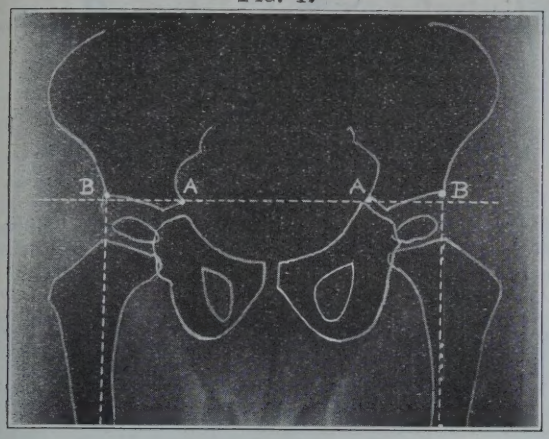
When to Suspect the Presence of a Congenital Dislocation of the Hip-joint.

The first thing to search for is something which will draw attention to the hip-joint, just as earache attracts attention to the ear. This something is late walking. Any child who is not walking at the age of 18 months, or who did not walk until some time after that date, should be suspected of having a congenital dislocation of the hip-joint, and the hip-joint should be examined.

The classical signs of a congenital dislocation depend on palpation; the head of the femur cannot be found in its normal place in Scarpa's triangle, but can be felt on the dorsum of the ilium.

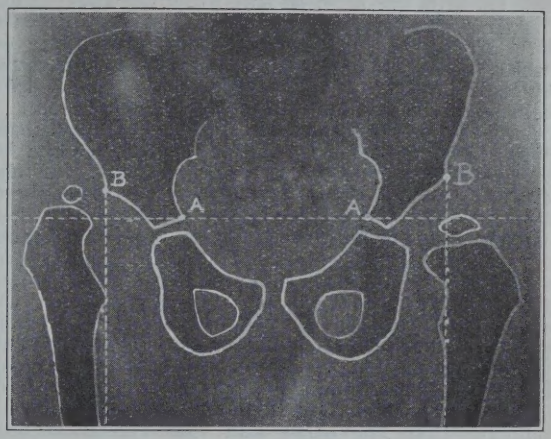
Palpation of the head of the femur in a baby is difficult, even when the child is docile, and I submit

FIG. 1.



X ray silhouette of the pelvic girdle in a normal child (adult male type).

FIG. 2.

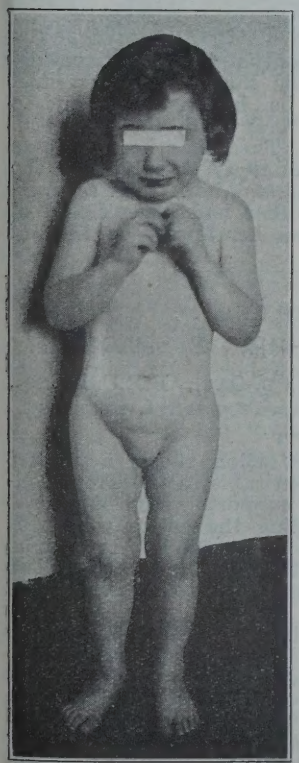


X ray silhouette of the pelvic girdle in a child with congenital dislocation of the hip (adult female type).

that the diagnosis can be made and ought to be made with certainty by inspection alone. Inspection will reveal three characteristic features: (1) the female profile; (2) dipping of the shoulder when the child walks; (3) shortening of the thigh.

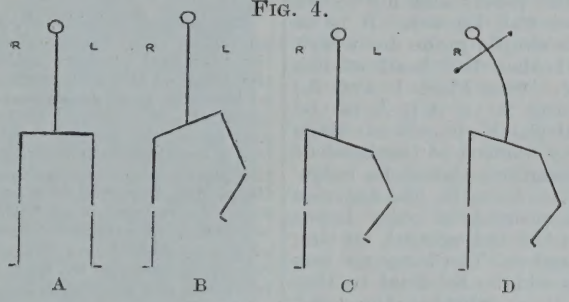
The female profile.—If a normal child is placed flat on the couch, supine and the lateral outlines of the trunk and legs are observed from above, its outline or profile resembles that of an adult male (Fig. 1). In the child with a congenital dislocation of the hip the outline approximates to that of an adult female (Figs. 2 and 3). Fig. 1 shows the X rays of a normal child, a boy aged 2; it has been taken with a soft tube, so that the soft parts as well as the bones are visible. Fig. 2 shows the X rays, taken in a similar manner, of a boy aged 1 year and 10 months with a congenital dislocation on the right side and a subluxation on the left. The difference in the outline of the body is clearly shown; it is most obvious on the waist line. There is an adult female profile on both sides in Fig. 2 and in Fig. 3. The trochanter, being further from the midline, gives the appearance of an increase in the width of the pelvis and the presence of a waist.

FIG. 3.



Photograph showing hip outline resembling that of adult female.

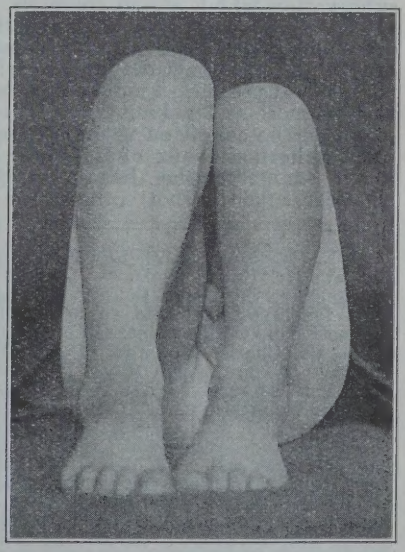
FIG. 4.



Trendelenburg gait.

Dipping of the shoulder when the child walks.—If the child has commenced walking, the mother will often volunteer the statement that the child has always had a painless limp. This is not really a limp, but a pecularity of gait which is hard to define. It consists of a swaying of the trunk towards the affected side whenever weight is borne on the affected leg. If the doctor concentrates his attention on the legs he will not observe the limp at all; if he watches the point of the shoulders the sideways sway of the trunk becomes apparent, because the shoulder dips down on the affected side when weight is borne on that leg. When the dislocation is bilateral the sway is first to one side and then to the other. The gait then becomes "rolling" and more obvious. When the normal individual takes one leg off the ground, say the left, and balances on the other, the weight of the trunk would naturally depress the pelvis on the left side because the supporting leg is not directly under the line of the body-weight. To prevent this, the muscles of the right hip-joint contract strongly and tilt the pelvis down on the right side. This is the normal (Fig. 4B). If for any reason the abductor muscles lose their power they cannot tilt the pelvis down on the right side, and the body-weight causes the pelvis to tilt down on the left (Fig. 4C); then the patient, to prevent himself from falling sideways to the left, throws his trunk over to the right, so that the line of the body-weight passes down through

FIG. 5.



Method of demonstrating the shortening of the thigh in unilateral dislocation.

the supporting leg (Fig. 4 D.). It is this tilt of the trunk towards the affected side when the affected leg is bearing weight that gives rise to the characteristic gait. In a congenital dislocation the abductor muscles, although powerful, are ineffectual, because they lack the fulcrum which normally is supplied by the head of the femur fitting into the acetabulum.

Shortening of the thigh.—In a unilateral dislocation the leg is always short, and the shortening can be made apparent without a tape measure. If the examiner takes hold of the legs of the recumbent child, one in either hand, flexes the knees fully then flexes the hips through 90 degrees so that the femurs are vertical, and approximates the two legs so that the feet are flat on the table and keeps them square with the trunk, he will see that the knee on the normal side projects upwards half an inch or so beyond the knee of the affected side (Fig. 5). This is any easy method of demonstrating shortening of the thigh. For a bilateral dislocation the test is of no value. The sign only demonstrates that one leg is shorter than the other and that the shortening is somewhere above the knee-joint, but for practical purposes it nearly always means in the young child a unilateral dislocation of the hip-joint.

These three signs, depending on inspection only, are sufficient in themselves to warrant a diagnosis of congenital dislocation of the hip-joint.

How to Confirm the Diagnosis by X Rays.

The X rays confirm the diagnosis, but the normal radiographic appearance of the pelvis and hip-joints in very young children is not well known. It is as well, therefore, to have some simple guide by which one can tell at a glance whether the head of the femur is in its normal place. (See Figs. 1 and 2.) Draw a horizontal line joining A to A; A is the innermost part of the ilium at the Y-shaped cartilage of the acetabulum. The bony nucleus of the head of the femur, as seen in the radiogram, should be below this line. Draw a vertical line from B, the anterior inferior spine (which is the prominent outer lower angle of the ilium as seen on the radiogram), cutting the horizontal line at right angles. The bony nucleus of the head of the femur should be internal to this line. These two lines will show whether the head of the femur is further up or further out than it should be. I have studied this in numerous X rays of normal pelves of children under the age of 4, and I have never seen the bony nucleus of the head of the femur above the horizontal line, although occasionally the vertical line may just cut into it. These two lines enable one to gauge whether a reduction is complete, and also point out the minor degrees of subluxation which are so common.

The purpose of this short communication is to draw attention to the fact that congenital dislocation of the hip-joint is not diagnosed early enough because the general practitioner does not know how to make the diagnosis. I submit that he should be able to diagnose the condition with certainty, by inspection only, if he makes use of the three signs enumerated above—namely, the female profile, the dipping shoulder, and the shortening of the thigh.

DONATIONS AND BEQUESTS.—Among other bequests the late Mr. Edwin Pope, of Mentone Lodge, Dorchester, left £5000 to the Dorset County Hospital, Dorchester, upon trust for investment and to apply the income in some distinctive charitable purpose in connexion with that institution.—Mr. Charles McLaren, of St. Anne's-on-Sea, Lancs, left £500 to the Oldham Royal Infirmary.—The University of Leeds has received a non-recurrent grant of £10,000 from the University Grants Committee to help the University to take in hand, with as little delay as possible, the purchase, extension, and equipment of the new premises for a men's hall of residence.—Mrs. Alice Mary Burnside, of Tollerton Hall, Notts, left £2000 to the Nottingham General Hospital to endow a bed or beds in the names of her husband and herself, £2000 to the Nottingham Children's Hospital for a similar purpose, £1000 to the Nottingham General Dispensary, £500 to the Nottingham and Midland Eye Infirmary, £500 to the Midland Orphanage for Girls, Nottingham, and £500 to the Gordon Memorial Homes for Destitute Boys.

Clinical and Laboratory Notes.

A CASE OF POLYDACTYLISM IN TWINS.

BY H. C. CRAVEN VEITCH, M.R.C.S. ENG.,
HON. SURGEON, HUNTINGDON COUNTY HOSPITAL.

TWINS both exhibiting polydactylism are, I believe, sufficiently rare to justify the report of the following case.

A healthy young woman of 25 gave birth to twin sons at her first labour. Not content with this munificence she had given to each twin six toes on each foot and one well-formed supernumerary finger, whilst one had also the rudiments of a second supernumerary finger.

X ray examination showed the condition to be as follows. A. B., the first twin, had upon his right hand two little fingers. The proximal phalanx was double and fused and from the interphalangeal joint two perfect and separate fingers grew. Each foot had six perfect toes, the little toe in each case being the supernumerary one. On the right side the metatarsal bone was Y-shaped and with each branch of the Y a toe articulated. The left side was slightly different; here the metatarsal was not definitely bifid, but was somewhat stout throughout, and at its distal extremity was expanded rather like the upper end of the manubrium sterni, with a perfect toe articulating with each side of the expansion. Except for the unnatural breadth of the foot the appearance was quite normal unless one counted the digits.

The second twin, B. C., had upon his left hand a supernumerary little finger, of which the bones were all perfect, the proximal phalanx articulating with the mesial side of the head of the fifth metacarpal. This finger was webbed to the first interphalangeal joint and protruded at an angle of 60° to the normal little finger. Upon the right hand, just above the metacarpophalangeal joint, was what looked like a small smooth wart. The mother told me that during the puerperium she noticed a small pedunculated tag of tissue hanging from this and that, thinking it of no importance, she snipped it off with scissors and was rather alarmed when it bled somewhat freely. This I take to be the bud of yet another finger. The feet present precisely the same condition as in A. B., with the exception that the sides are reversed, the Y-shaped metatarsal being on the left side.

The twins are now 20 months old and I have just removed the supernumerary fingers, as it seemed likely that they would be in the way and a nuisance as the children grew older. I am still undecided about the feet. There has been no case of polydactylism in the mother's family, but the father had one brother who was born with a supernumerary thumb. His mother had never heard of any previous case in either her family or that of her husband.

A NOTE ON THE TRENDELENBURG POSITION.

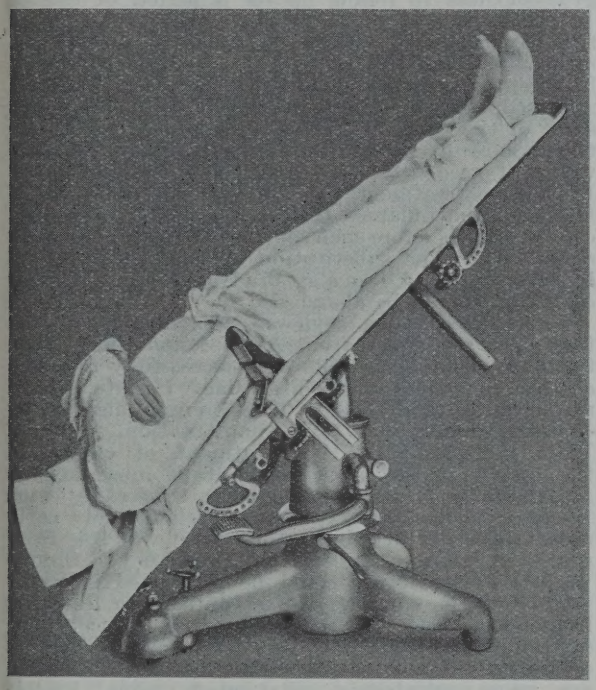
BY R. OGIER WARD, M.CH. OXF., F.R.C.S. ENG.,
ASSISTANT SURGEON, ST. PETER'S HOSPITAL, LONDON.

THE accompanying illustration shows a subject maintained on the operation table in the Trendelenburg position by means of supports which fit against the iliac crests, thus holding the entire weight of the patient by fixing the bony pelvis. It will be noticed that, although the table is tilted to the fullest extent, no shoulder-rests are used, nor are the knees flexed.

On first principles this is clearly the best way to support a patient. But I was led to adopt this method and to design these pelvis supports which were made for me by Messrs. Allen and Hanbury, because I have seen several patients who have suffered from a partial palsy of the ulnar nerves, following operations conducted in the Trendelenburg position. They have all been elderly men operated upon for diseases of the prostate and bladder. The usual sequence of events has been that, on recovery from

the immediate effects of the operation, they have noticed a numbness of the hands and forearm, precisely confined to the distribution of the ulnar nerves. This has in several cases persisted for two or three months, but so far as I know has always ultimately cleared up; there has never been motor palsy, but only numbness and impaired sensation. It is probable that many surgeons and anæsthetists have met with examples of this trouble. The explanation of it is, I believe, as follows.

If shoulder-rests are used, the patient's shoulder-girdle is firmly fixed. When the operation table is tilted the weight of the body forces the upper part of the thorax, which is, of course, conical in form,



Patient in the Trendelenburg position, showing supports.

into the shoulder-girdle. As a result of this, the last cords of the brachial plexus, consisting of the eighth cervical and first dorsal nerves, are compressed against the first ribs and thus may be damaged.

It will be seen that this condition cannot be avoided by placing padding over the shoulders, for if the damage was done by the direct pressure of the shoulder-rests upon the brachial plexus, then the lesion produced would be one affecting the upper cords—namely, the fifth, sixth, and seventh cervical nerves, injury to which would produce a palsy of the Erb type. I do not think that this has ever been recorded, whereas, in my experience, the injury has always been definitely confined to branches of the eighth cervical and first dorsal nerves.

There is a further advantage to be gained by supporting the patient through the bony pelvis—namely, that the respiratory movements of the upper thorax are in no way restricted. And this must surely be very desirable, especially when a very extreme Trendelenburg position is used as, for example, in some gynæcological operations. The patient is thus elevated in order to empty the lower part of the abdomen of its contents and the whole weight of these falls against the diaphragm, with the result that its value as a muscle of respiration is greatly impaired, and the patient has to depend almost entirely upon costal movements. Anything, therefore, that can be done to allow of freedom of thoracic movements is clearly of advantage.

These pelvis supports have now been used at St. Peter's Hospital for more than two and a half years, and are found to be very satisfactory. Admittedly, it is necessary to fit them carefully to each case, but there is no more difficulty in this than there is in the correct adjustment of shoulder-rests. They do not inconvenience the operator in any way, either for midline incisions or for operations in the iliac fossæ. The disposal of the patient's arms requires attention, and if they are placed at the sides, it is necessary to put thick pads of wool underneath the elbow-joints. The supports can be fitted to any operation table of the type illustrated.

A CASE OF "EALES'S DISEASE"

(RECURRENT INTRAOCULAR HÆMORRHAGES).

By Allister M. MacGillivray, M.B., Ch.B. St. And., D.O.M.S.,

SURGEON TO THE DUNDEE EYE INSTITUTION.

Eales's disease, which was first described by Henry Eales in the *Birmingham Medical Review* of 1880, is characterised by the occurrence of hæmorrhages into the retina and vitreous in young adults. These hæmorrhages tend to be recurrent, and the disease is specially prone to attack young male adults, although females are by no means exempt. Both eyes are usually involved sooner or later. In the earlier attacks the hæmorrhages may clear up with restoration of good vision, but the tendency is for permanent defects, or complete loss of sight, to supervene after several occurrences, as a result of the development of dense vitreous opacities, cicatricial bands in the retina and vitreous (retinitis proliferans), and detachment of the retina.

The subjects of Eales's disease frequently suffer from periodic attacks of epistaxis and chronic constipation, but the great peculiarity of the condition is that no definite constitutional cause for it has ever been discovered, the heart, the lungs, the blood-vessels, and the kidneys usually being normal. Various suggestions as to the causation have been put forward by different authorities, but as yet none has proved convincing. It has been ascribed to anomalies in the coagulability of the blood, the coagulation time being either raised or lowered; the action of a tuberculous toxin; myocarditis; enterogenous auto-intoxication; disturbances in the functions of the endocrine glands, &c. Syphilis has definitely been eliminated as a causative factor. The treatment is most unsatisfactory. Laxatives, potassium iodide, calcium lactate, injections of horse-blood serum, and many other methods of treatment have been advocated, but in the majority of cases all efforts in attempting to prevent recurrence of the hæmorrhages have proved useless. A few cases, however, have been reported, where for no apparent reason the hæmorrhages have ceased after varying intervals of time, with the restoration of good vision.

The following is a case of Eales's disease in a young male adult, the only abnormality found being a lowering of the coagulation time of the blood.

A man, aged 28, was first seen by me on May 20th, 1924. He complained of a dense cloud over the left eye which came on suddenly the previous morning. Up to that time the eyes and eyesight were perfect, and there was no history of serious eye troubles in any other member of the family. He was not a "bleeder" and, as far as he knew, none of his family was, or had been, bleeders. The vision of the left eye was reduced to perception of light only. On examination the vitreous was found to be filled with blood, obscuring any view of the fundus. The vision of the right eye was 6/6. This eye was normal in every respect, except for 2 dioptres of simple hypermetropia.

He was referred to his own doctor, who reported that there was nothing in his general condition to account for the hæmorrhage. He was then put on a course of potassium iodide. The hæmorrhage began to clear up, and a month later

the fundus was with difficulty seen, but no abnormality observed. Three weeks later another hæmorrhage occurred, again filling the vitreous and obscuring the fundus. His general condition was once more very carefully investigated and again was reported to be normal, there being no evidence of cardiac disease, tuberculosis, or intestinal auto-intoxication. The coagulation time of the blood was tested and proved to be slightly lowered. With a view to preventing any further recurrences, calcium lactate was substituted for potassium iodide.

The hæmorrhage was very slow in clearing up, and it was not until some six months later that a clear view of the fundus could be obtained. During these six months no recurrence of the hæmorrhage had taken place, but he had suffered from several slight attacks of epistaxis. The vision of the eye was 6/60. On examination a narrow sickle-shaped band of white fibrous tissue was seen arising from, and obscuring, the optic disc. This fibrous band extended towards the macular region and projected for some distance into the vitreous. The macula itself was not involved, the band curving below it to end in a fine point some two discs breadth beyond. Several newly formed blood-vessels were to be seen curling irregularly over the white mass and projecting into the vitreous.

A vitreous hæmorrhage usually becomes completely absorbed, but in certain cases, such as in Eales's disease, organisation takes place. This is due to the action of fibroblasts derived from the only mesoblastic tissue in the retina, that forming and surrounding the central retinal blood-vessels. As a result of this organisation, bands of white fibrous tissue develop, along with adventitious blood-vessels derived from the central retinal system, and the condition is known as retinitis proliferans. These bands project into the vitreous from the region of the optic disc and may be attached at their extremities to the retina. By cicatricial contraction, the bands may drag upon the retina, with the result that the retina becomes detached, causing complete loss of sight.

Two months later another relapse occurred. Injections of hæmoplastin were instituted, but relapses recurred every month until December, 1925, when by focal illumination a large blood-stained detachment of the retina could be made out. The right eye remained normal.

The patient was not seen again until Feb. 8th, 1928, when he was examined at his house. He was in a very melancholic condition and had not been outside his own home for nearly two years. Consequently examination was difficult and his statements inaccurate. As far as could be ascertained there had been deterioration of the vision of the right eye for some time past, culminating in an attack of sudden blindness in the beginning of January. It was impossible accurately to judge his visual capacity, but he was able to make his way about the house slowly by himself, though quite unable to do any reading. On examination two broad bands of white fibrous tissue could be seen arising from, and obscuring, the optic disc and projecting into the vitreous. One of these bands extended nasally, the other temporally, each to terminate in a fine point attached to the retina. The macular region was completely obscured by the temporal band. A few newly formed blood-vessels could be seen coursing irregularly over these white masses, also several patches of recent hæmorrhage.

An interesting feature of the case is that in May, 1926, the patient was admitted to hospital for special investigation as regards his nervous system. He was under the care of Dr. W. E. Foggie, to whom I am indebted for the following notes.

He was found to have retention of touch in the right arm, the right side of the trunk, and the right leg, but analgesia and thermo-anæsthesia over the same area. There was some stiffness and weakness of the left leg. With the knowledge of recurrent intraocular hæmorrhages in the left eye the condition was diagnosed as a hæmorrhage into the spinal cord in the lower cervical region—a hæmatomyelia, with probably some pressure on the pyramidal tracts of the left side. The Wassermann was negative. The electrical reactions of the limbs were normal. The other systems were normal. Blood pressure: 140/105. Blood coagulation time: 75 seconds—i.e., lower than normal. The patient was very nervous and his general outlook gloomy.

The prognosis is grave, the probability being that a detachment of the retina will eventually take place, as in the left eye, owing to cicatricial contraction of the white fibrous bands.

Medical Societies.

MEDICAL SOCIETY OF LONDON.

ADVANCES IN THE TREATMENT OF CANCER OF THE CERVIX.

A MEETING of this Society was held on March 26th, with Mr. H. W. CARSON, the President, in the chair. Opening a discussion on the treatment of cancer of the cervix, Dr. HERBERT SPENCER spoke of the futility of relying on statistical inquiries based on insufficient data, and appealed to younger gynæcologists to follow up for a period of five or 10 years the first 10 or 20 cases they saw, putting full particulars on record, in order to replace the misleading statistics of to-day. No growth should be accepted as cancerous unless it had been examined microscopically by experts in gynæcological pathology; some of the cases of "cancer" recorded might owe their non-recurrence to their non-malignancy. Advance was still needed in the early recognition of cases. Preventive treatment was difficult, but irritation of lacerated and inflamed tissues was likely to produce cancer, and therefore such sources of irritation must be dealt with. The substitution of total for sub-total hysterectomy had been a great advance, and the latter operation should be abandoned.

Dr. Spencer then reviewed the history of the treatment for cancer from Anglo-Saxon times down to 1828, when James Blundell successfully removed a cancerous uterus for the first time. Despite hopeful researches, such as those of Thies on immunisation by cancer-albumin and cancer-implantation, and of Blair Bell on lead, the treatment of cancer of the cervix at present resolved itself into excision or irradiation. High amputation, preferably with Byrne's electro-cautery, was excellent for early cases, especially in elderly women; it was free from risk and allowed subsequent pregnancy. Simple vaginal hysterectomy could be performed in many ways, but the cautery had advantages in lessening hæmorrhage and the frequency of recurrence. The immediate mortality was very low, and the vaginal operation did not interfere with marital intercourse nor cause scar-hernia. Extended vaginal hysterectomy consisted in more extensive removal of the tissues with the help of paravaginal incisions. Its mortality was higher than the simple operation, but had been reduced to 2·7 per cent. by Pehan. It was important that the peritoneum should be carefully closed, as gauze drains might set up adhesions which later produced obstruction. Like the abdominal operation, extended vaginal hysterectomy interfered with marital intercourse. The chief advantage of abdominal operation lay in the removal of infected glands, though it was possible that extensive removal of glands and cellular tissue had disadvantages other than that of increasing the operation risk. Simple abdominal hysterectomy was useful where there were complications or where weakness or advanced age made extended operation inadvisable. Wertheim's operation allowed wide removal of tissue, but had a high mortality and late sequelæ. The mortality-rate had been lowered by gauze drainage, but this favoured hernia of the scar and intestinal obstruction. In about two-thirds of the patients the glands were not cancerous, their removal increased the danger and could never be really complete, and it appeared that cancerous glands could free themselves from cancer, especially with the aid of irradiation. Combined abdominal and vaginal hysterectomy had some advantage in lessening the exposure of the peritoneum and the danger of infection. Treatment could be eclectic, and no one form was suitable for all cases. The most hopeful method for the future was irradiation.

Treatment with Radium.

Dr. MAX CHEVAL (Brussels) said that he used large quantities of radium emitting rays with a wave

length corresponding to a tension of 2,000,000 volts. Slosse and Reding of Brussels had shown that the blood-sugar curve, after ingestion of dextrose fasting, was quite distinct in the sufferer from malignant disease. Her normal blood-sugar was slightly higher than that of the healthy person, and the maximum after taking dextrose would be between 0·25 and 0·26 per cent. occurring one hour instead of half an hour after ingestion and taking two hours to reach the resting level again. The blood-sugar curve retained this "malignant" character after operative cure, but after cure by irradiation, either by X rays or gamma rays, the curve returned to normal. If irradiation had effected improvement but not cure, the degree of return of the blood-sugar curve towards normal was a measure of the improvement effected, and the curve would betray a recurrence before this could be detected clinically. Similar information was given by the acid base level. The pH increased in malignant cases, and the alkalinity might rise to 7·57 in acute cases. After operative cure it remained high; after cure with radium it returned to normal. Exactly similar results had been obtained for the ionised calcium of the blood.

After outlining earlier methods of radium treatment and his reasons for discarding them, Dr. Cheval described his present method.

The apparatus treats two patients at once, placed in bunks, at right angles to each other, with the radium between them. Four grammes of radium element are placed in the centre of a mass of lead in which canals had been drilled to permit emission of radiations upwards and downwards. The element itself lies in a square box, 4 × 4 cm., made of steel and copper, equivalent to 1 mm. of platinum. The radium is thus spread out on a surface of 16 sq. cm. The localisation of the rays is given by the mass of lead, and the rays which are not to reach the patients must pass at least 8 cm. of lead. Above and below the radium is a canal in the shape of a truncated cone with the small opening near the radium and the large end looking towards the patient. The screenage is 1 mm. platinum, 5 cm. aluminium, and 4·5 cm. wood, and the minimum distance between the radium and the skin is 12 cm. The area of skin irradiated is 12 sq. cm.

The results, said Dr. Cheval, were controlled by accurate iometric measurements by Prof. Picard. To treat a deep-seated abdominal growth six areas were successively irradiated, two on the front, two on the back, and one on each side. The resulting area of evenly radiated tissue was a polyhedron equal to a sphere of 22 cm. diameter. The radiation extended far beyond the affected zone and its lymphatics. The effect on a dry skin was slight dermatitis with brown pigmentation and a few vesicles. Nearly all the hair fell out in three or four weeks, but was restored within six months. On a moist skin the reaction would be more acute, but harmless. There were no subcutaneous reactions. Cartilage and bone offered no obstacle to these rays; the gamma rays went through them without causing necrosis. The general effects were never serious. There was usually slight tiredness and occasionally a little diarrhœa or vesical irritation. The urine had been carefully collected and analysed but showed no abnormality, nor had there been any alteration in the composition of the blood even with irradiations as strong as two and a half curies. Thus, the human organism could stand very large amounts of irradiation, up to 480,000 mg. hours of radium element, corresponding to 900,000 mg. hours of radium bromide.

To test the clinical effects daily biopsies had been performed as long as possible, and Dr. Cheval produced microphotographs showing the invasion of tumours by leucocytes and their absorption. The method had only been in use two years, and therefore cures could not yet be claimed, but statistics showed that at least 30 per cent. of all cases treated by irradiation were cured. The new method should raise that figure considerably, and the treatment deserved to be regarded as something more than a palliative for hopeless cases.

Discussion.

Dr. F. J. McCann thought that cancer was a general disease with local manifestations. Patients usually had a period of subnormal health before the growth appeared, and the occasional failure of extensive operation even in early cases convinced him that there was something in the patient which determined cure or disappointment. It was well known that unless a patient's health improved, and especially if she did not gain in weight after the operation, the prognosis was poor. The individual type was important; he had never seen a breast cancer cured in a fat woman, but generally expected success with a thin dried-up one.

Dr. Malcolm Donaldson said that radium was the only treatment worthy of the name for inoperable cancer; its local effect was acknowledged by everybody. The problem of the deeper tissues and glands was being met by X-rays, intra-abdominal radium, and the application of large quantities of radium outside the body as Dr. Cheval had described. The results of radium in operable cases compared with those of surgery were about equal. The disadvantages of surgery were that it took years to learn the technique, and the mortality, even under the most skilful hands, was considerable—15·8 per cent. according to Victor Bonney's figures. Few cases were really suitable for operation, and many patients were deterred from seeking advice by the fear of it. Radiotherapy had the advantages that the initial mortality was negligible; it was suited to nearly every case of carcinoma of the cervix except those with fistula and moribund patients. The technique could be rapidly acquired by any gynæcologist; the time in bed was reduced and the fear of operation lessened. On the other side, there was as yet no scientific evidence that radium dealt with the glands as efficiently as other methods. At St. Bartholomew's the method was to apply about 22 needles, containing 50 mg. of radium element. The thickness of the walls—5 mm. of platinum—filtered the rays. The needles were kept in place by a gauze pad soaked in flavine, and left for 144 hours. To gain the knowledge requisite for judging which form of treatment gave the best results, it was necessary to concentrate on discovering the effect of the rays on the individual cell. Working with tissue cultures at Cambridge, he had found that more damage was done by small doses over a long period than large doses for a short period. Gamma rays had a selective action on all quickly growing tissues; sections of growths after treatment showed rapid swelling and breaking down of the malignant cells, while normal tissue cells remained intact. He had used an intra-abdominal technique which involved packing the whole pelvis with gauze and leaving the radium in place for about a week; there had been a good deal of reaction in his cases, but all ten patients were now alive after two years. He was giving the method another trial without the packing; a patient who had had 40 mg. of radium element in needles, each one sewn to the peritoneum, experienced little reaction, but the method was still on trial. It was a great mistake to talk about cure, and he based his statistics on length of survival. Of operable cases, he had 16 living and had lost 7, of borderline cases 3 were living and 6 had died, and of inoperable cases 48 were living and 112 had died. He had given up the extraperitoneal operation because it was a blunt dissection and led to discharge; it was a mistake to apply radium to damaged tissues. The combination of the Wertheim operation with radium had not been very successful.

Dr. Douglas Webster regretted that the value of distance radium therapy was insufficiently recognised in this country; it had given good results on the Continent not only in gynæcological cancer, but in gastro-intestinal, mediastinal, and cerebral growths. Post-Wertheim X ray treatment had prevented recurrence after three or four years in 50 per cent. of his cases, and showed a much lower operation mortality-rate. According to Meyer, of Tübingen, the pre-operative use of radium reduced the mortality from abdominal sepsis to less than one-half of what it had been; a considerable number of

inoperable cases had been rendered operable within a few months, and the percentage of recurrences had been much lessened.

Dr. S. FORSDIKE remarked that the application of radium to the vagina and uterus could not affect the glands in the iliac region; possibly external application might overcome this difficulty. The technique was not easy, and radium was much misused. Penetration of lymphatic spaces in the growth during the insertion of needles facilitated metastasis.

Dr. G. E. VILVANDRÉ ascribed the superiority of radium over X rays to the much higher voltage equivalents which it represented. If X ray installations could be constructed to give an output of 2,000,000 volts, they might give results even better than those obtained by Dr. Cheval. He thought that an alleged predisposition to cancer was often due to an undiagnosed tumour and a mild carcinomatosis.

Dr. A. GOODWIN said that in many borderline cases where the growth was irremovable the combined method was the best. When it was impossible to perform Wertheim's operation the glands should be removed and all the vessels ligated; the mortality from this procedure was almost nil. The use of radium after this was better than its use alone. He had known needles to be lost in a patient's body, and an elderly patient had died from radium burns and necrosis leading to rupture of the femoral artery, although the dose had been quite moderate.

Dr. SPENCER and Dr. CHEVAL replied.

ROYAL SOCIETY OF MEDICINE.

SECTIONS OF ODONTOLOGY AND ELECTRO-THERAPEUTICS.

A COMBINED meeting of these Sections was held on March 26th under the presidency of Mr. W. RUSHTON (Odontology) to discuss the subject of the

PULPLESS TOOTH.

Mr. FRANK COLEMAN opened the debate from the dental side. He said the pulpless tooth should not be termed a dead tooth, for its periphery—i.e., the cementum — retained some vitality through the periodontal membrane. There was a separate blood-supply and therefore probably also a separate nerve-supply for the pulp of the tooth. When the pulp was anæsthetised by applying a local anæsthetic directly to it, the periphery of the tooth was not rendered anæsthetic, and whereas the pulp could be removed painlessly, the tooth itself could not be extracted without giving pain. On the other hand, by injecting a local anæsthetic around a tooth, painless removal became possible, yet the pulp would retain a measure of sensibility.

The main principles concerned in the treatment of teeth with exposed live pulps or teeth containing dead pulps were: (1) To remove, as far as possible, every trace of pulp tissue. In teeth having live pulps the desensitisation of the pulp must first be assured by means of a local anæsthetic or a caustic. If the latter was used, a few days must be allowed to elapse to bring about complete devitalisation of the tooth pulp. (2) To cleanse the root canal or canals of the tooth and to treat the periapical tissues via these channels. (3) To fill the cavity of the tooth when the periapical tissues had ceased to discharge through the canal of the tooth and had formed a scar at the tooth apex. Most dental surgeons, said Mr. Coleman, recommended the filling of the roots of the tooth as well as the cavity in the crown of the tooth. His own practice was only to fill the cavity in the crown of the tooth—in other words, the pulp-chamber. The periapical tissues could then be further treated if and when necessary, the empty root canal serving as a passive channel down to those tissues. The method by which the implanted portion or root of the tooth was treated before its restoration might have a considerable effect on the after-history. The technique should be carried out under as aseptic conditions as possible. He favoured the use of non-irritating antiseptics in the dry or solid form, such as iodoform, rather than in the liquid state. The tooth cavity should only be filled when the periapical tissues had scarred and so had ceased to discharge; to close the canal or cavity of a tooth before the periapical tissues had ceased to discharge was to court disaster. It had recently been shown that pulpless teeth caused less disturbance to their surroundings when their roots were not filled to their extremities than when they were completely filled. Bulleid regarded the granuloma at the end of the root of a dead tooth as a defensive mechanism, and said that it was more often associated with a partially filled root than with a more completely filled one. The reason why so many untreated dead teeth remained quiescent was that their infected canals lay open to the mouth; hence they could discharge exudative products, which, if pent up, would at some time form an abscess. Mr. Coleman regarded a pulpless tooth as a pathological entity; it should be considered an irritant to the tissues. It was not quite simple to decide whether such a tooth should be extracted. If it was important for mastication, reasonable efforts must be made to preserve it, though in so doing the leading principles of surgery must not be disregarded. Many such teeth eventually caused abscess, and they were invariably somewhat tender on percussion. The abscess might open on to the mucous or cutaneous surface and go on discharging through a sinus. Nature's safety-valve for dead teeth was usually on the gum near the apex of the tooth, or between the tooth and its socket, the discharge in the latter case appearing at the side of the tooth. The least harmful form of untreated dead tooth was probably that with a sinus on the gum or at the side of the tooth and with a pulp chamber open to the mouth; in such case the material formed was probably swallowed and largely destroyed by the intestinal juices. The least harmful form of treated dead tooth was that with a relatively clean root canal. Clinically, these teeth were always a little tender on percussion as compared with normal teeth, also less translucent, often presenting slight gingivitis at the gum margin. The root of a deciduous tooth might be so far absorbed as to render the tooth pulpless, yet it might be retained in this condition for many years without apparent ill-effect, though its retention was to some extent governed by the presence or absence of its successor. In elderly people the tooth pulp might undergo concentric calcification until, finally, the whole pulp chamber and the root canal became filled with a mass of calcified tissue. Even such teeth might not cause ill-effects on their surroundings.

Chronic irritation, such as erosion or attrition, would sometimes lead to a deposition of a protective dentine over the pulp. Some day, perhaps, the dentist would be able to promote and control this process. Mr. Coleman did not feel any leaning towards excising the end of a root involved in periapical destruction. The extent of disease in a root could not be diagnosed, as no line of demarcation was formed between the living and the dead portions of the tooth. It therefore resolved itself into the empirical removal of a certain amount of necrotic root. He regarded as only palliative such processes as the opening and scraping of sinuses connected with dead teeth and the injection of drugs through those sinuses; the cause still remained. Unless a pulpless tooth was completely removed a source of infection was present as great as, if not greater than, the original source of mischief.

Mr. OWEN MORPHY said that probably the pathologist would condemn 95 per cent. of pulpless teeth, but the clinician's verdict would not be so sweeping. He himself inclined to the removal of pulpless teeth, especially when definitely septic, though he realised there were occasions when an attempt to save even a septic tooth should be made—for instance, when the patient was robust and well fortified with natural resistance. The partial denture, especially when made of vulcanite, was a prolific source of oral sepsis,

largely because it did not receive the care needed to make it comparatively innocuous. The pulp of a tooth was infected even when there was but a tiny carious cavity. In preparing cavities, the dentist probably never quite removed the infection by mechanical procedures. There were many patients with many large fillings whose pulps were vital, and in the absence of the dead tooth the pathogenicity of these pulps was ignored. In dealing with an infected tooth, the surgeon was mainly concerned with the organisms in the lumen of the canal and any there might be outside the apex in the periapical space; in the latter position the defensive mechanism of the blood stream was able to act. He was a believer in the value of ionisation for the sterilisation of the parts of the root not accessible to mechanical and chemical measures; the current carried the ion of zinc or iodine through the finest channels at the apex of the tooth. Seldom could a greater current than 2 milliampères be tolerated by the patient, but as the area was so small the concentration was really considerable. By employing the positive pole, Russ had shown that organisms could even be withdrawn from a cavity, quite apart from the lethal action of the ions injected. Weston Price, of America, had clearly shown that it was the tooth which had no defensive granuloma that was the dangerous one, as a granuloma was probably an expression of the patient's resistance. Clyde Davis, in a histological analysis of 100 root-filled teeth, in which the filling stopped short of the apex, found that in all cases where the canals were not infected and caustic drugs had not been used, cementum had grown into the apical foramina and quite occluded them. Where infection had occurred, cementum had grown into the foramina, but the occlusion was not perfect. Instrumentation at the apex should therefore be avoided, so as not to injure the vital cells in the periapical region. Also it seemed advisable to devitalise and remove as little of the pulp as possible. The great difficulty was to prevent reinfection of the scar from the cavity end; in this position Mr. Morphy considered that the solid, non-irritating root-filling was safer than a column of gases. The filling of multiple foramina by artificial means was admittedly impossible. He contended that X rays, by indicating the radiolucent area, gave a line of demarcation for the dentist to take as his guide in doing apicectomy. This operation would fail if the scar was formed in contact with the infected dentine.

Dr. H. M. WORTH said that no intrinsic radiological changes were associated with a dead tooth, but often the appearances in or around it were helpful. Among the certain signs that a tooth was pulpless were the following: the presence of filling material in the root canal or pulp chamber, which material was usually metallic, and showed up well in the skiagram; the presence of osteitis with bone destruction or rarefaction only at the apex of the tooth, with loss of continuity in the lamina dura; the presence of filling involving the pulp chamber; the fact that the pulp chamber and root canals had become completely calcified; the presence of a large cavity extending into the pulp chamber, with no other evidence, warranted the conclusion that the pulp was dead. There were also a number of other indications.

Dr. MURRAY LEVICK spoke of the general raising of the bodily resistance by means of artificial light to the skin. This so stimulated the formation of vitamin D that the patients waged a much more successful combat against their infection. But the case was far otherwise if irradiation were applied to the buccal or other mucous membranes; and certainly the rays should not be applied to the throat. Red and ultra-red rays he had found very efficacious in clearing up infective conditions; they would probably be increasingly used for sepsis in the future. They should not be directed upwards through the palate.

Mr. A. T. PITTS considered that the only place for a pulpless deciduous tooth was the dust-bin; treatment of such he did not regard as legitimate dentistry. It was necessary to differentiate between a tooth devitalised by the dental surgeon and one which was already dead. Treatment should be antiseptic rather than aseptic, asepsis being impossible. The treatment of a pulpless tooth was a dental luxury rather than a dental necessity. Removal of septic teeth was a measure of wisdom. When people had had many teeth filled the question of a mass infection always arose. The treatment of a pulpless tooth should be checked by radiography. Treatment of a pulpless tooth was justifiable if careful selection and patience were exercised.

Dr. MEYRICK JONES reminded the meeting that pathological changes as seen in radiograms were not produced quickly, especially in bone; they were the results of months of morbid change. He did not agree that apical granulations were a sign of immunity. A pulpless tooth, even if it showed no pathological change, might at any time become a secondary focus in a general septic state. If in a young adult a pulpless tooth was left in, there should be a periodical report by the radiologist.

Dr. A. LIVINGSTON did not think it was possible to diagnose the vitality, the pulplessness, or the presence of pulp in a tooth by radiographic means. The contention based on the presence or absence of the lamina dura on the apex of the tooth fell to the ground, for the lamina dura was not continuous. He joined issue with Mr. Coleman in regard to what he said about unfilled canals; he did not regard the method as satisfactory, for in the event of an accident to a tooth so treated, it was unable to resist infection; certainly it could not resist caries. If a tooth was septic, all traces of sepsis must first be removed. Apicectomy was a success, but it must be premised that the case on which it was performed was a chosen one, and that it was carried out with the best technique.

Dr. J. F. BRAILSFORD said that dead organic matter from a dead tooth brought into association with the circulating blood through the dentino-cemental foraminæ was liable, even if sterile when the pulp was extirpated, to be infected by any organism there might be in the blood. It had been shown that, whatever medicament was used in the treatment of infected apices, any dressings left in for 48 hours were infected. Even when great care had been taken, root-filled teeth might be a source of great danger. Weston Price considered that 10 per cent. of the teeth which had septic roots gave no radiographic indication of the fact. He spoke of the various risks of misinterpretation of dental skiagrams, and showed a large number of slides.

Mr. ST. J. STEADMAN, speaking of apicectomy, said his object was not, as Mr. Coleman said, to remove the portion of the root which was dead, but to deal with the last ¼ in., which was the important part. For this operation a large incision was needed, and a flap. He agreed about the importance of carefully choosing the cases for filling. If teeth were chosen for the operation which already had pockets round and the periodontal membrane half-dead, success could not be expected; it was more hopeful in teeth otherwise healthy in the incisor region.

Mr. NORMAN GRELLIER held that a pulpless tooth ought not to be retained; inflammation might exist at the apex of such a tooth without causing symptoms, and it might not be detectable by radiography.

Dr. A. C. JORDAN said he felt considerable sympathy with dental surgeons who tried to save dead teeth. The radiologist should confine his efforts to describing and reporting on what the skiagram showed; he should not attempt to prescribe treatment. He believed attempts to save a pulpless tooth were foredoomed to failure. He hoped dental surgeons would not lose any opportunity coming their way to impress upon patients the importance of a proper dietary.

Dr. G. B. BATTEN agreed that the majority of pulpless teeth, if retained, sooner or later caused trouble, though not all of them. Much depended on the vigour and resistance of the particular person.

The PRESIDENT agreed that it depended very largely on the general health of the individual whether trouble arose from retention of a pulpless tooth.

MEDICO-LEGAL SOCIETY.

A MEETING of this Society was held on March 22nd, with Sir WILLIAM WILLCOX, the President, in the chair.

Dr. GERALD SLOT read a paper on

PAIN IN ITS MEDICO-LEGAL ASPECTS.

He said that pain, like insanity, was very difficult to define. Cicero had regarded it as a disagreeable movement in the body independent of the senses, and Erb's view that every increase of ordinary sensory stimuli was capable of producing pain when it attained a certain intensity had been widely accepted. Dr. Slot then outlined, for the benefit of non-medical members, the anatomy and physiology of the pain mechanism, and referred to the work of Pavlov on conditioned reflexes. From the medico-legal aspect, he continued, pain and the absence of pain were of great importance. It was important to decide whether the pain complained of was real or not, whether it had been caused by the accident, and how great was the extent of incapacity. There was a definite condition of over-reaction to pain—Roussy's "syndrome thalamique"—in which there was intense idiopathic pain with increased peripheral sensitivity. The rules laid down by the law courts seemed to be that if a workman were unfit through existing pain or disease to do the work on which he was engaged, or if he broke down or died in consequence of some event which would not have affected healthy persons, his dependents could claim compensation. Pain which persisted as a result of some condition which might have been cured by more effectual medical skill was regarded as incapacity for which compensation was payable. It was for the employer to establish that the treatment was bad. The same rule seemed to apply to a man who refused an operation for the relief of pain caused by an accident. The onus of proof that pain resulted from an injury was on the claimant, whether the pain was mental or physical. (*Joy* v. *Morton*, 1922). It was not necessary to show that the pain was the natural consequence of the injury or accident so long as the chain of causation was unbroken by any new act. It was in this connexion that medical evidence was of the greatest importance and conflict between medical witnesses most likely to occur. Different conditions associated with pain—e.g., erysipelas, bronchitis from influenza due to debility after the accident (*Thorburn* v. *Bedlington Coal Co.*)—had all been held to constitute good claims for compensation.

Pain Without Obvious Physical Cause.

Since pain might be due to a memory or thought which produced the same effect as an obvious factor, it was very difficult to contest a claim. In *Eaves* v. *Balenclytach Colliery Co.*, 1909, it had been held that incapacity arising from nervous defect or loss of will power produced by an accident did not deprive a workman of his right to compensation. It had been found further that if a man honestly believed that he was incapable of work, as a result of pain or neurasthenia resulting from his accident, he must remain compensated even though evidence could be adduced that employment would facilitate his recovery (*Wall* v. *Steel*, 1915). Brooding over the effects of an accident had been held not to be incapacity within the Act. A very large number of cases of pain in the back had been placed on record.

A strong, active man was riding in a first-class carriage when a slight collision occurred. He was somewhat upset, but was soon able to walk to his business. The next day he felt an acute pain in his back, which ultimately confined him to the house. He was treated and began to improve. The pain was due to a slight rupture of the ligaments in the lumbo-sacral region. Possibly no pain had been noted at the time because there had been no exudation.

As Page had pointed out, it was significant that in hospital tende ness of the back was not a prominent symptom of disease of the spinal cord, whereas in injury and malingering it was often made the outstanding feature of the case. Fear of paralysis might cause an honest exaggeration of the symptoms. In attempting to analyse the pain complained of, the doctor must observe the gait and seize opportunities to stretch the dorsal fascia while the patient was off his guard, as by extending the knees in the sitting position. It was important to know if there had been any constitutional symptoms prior to the accident. Other causes must be considered, such as pre-existing arthritis, spinal curvature, flat-foot, and metatarsalgia.

Collins, Master of the Rolls, had laid down the law in *Lloyd* v. *Sugg* on the matter of the nervous subject. Increased pain, or pain greater than one might reasonably expect, caused by nervous shock, in no way diminished the defendant's liability—e.g., the actual shock and pain resulting from a railway accident might be the same in a nervous, delicate lady as in one of sound health, but the resulting injury would be greater in the former. There was no doubt that the nervous temperament, so increasingly common nowadays, would receive pain impulses in a different manner from the non-nervous type and that the mode of spread would be different also. The medical examiner must realise the fundamental differences in the make-up of human beings. Pain and other disorders, as G. Guinon had stated, arose not so much from the immediate cause as from a state of the nervous system such that the exciting cause was able to provoke in it nervous disorders. Pavlov had separated the psychotic from the hysteric dog on purely physical grounds, and shown that a balance between excitation and inhibition was responsible for some of the responses to external stimuli. Fear, hunger, grief, and pain each played their part in securing a different reflex and altering the stability of the nervous system in experimental animals, in whom there was no question of malingering. Pearce Bailey had well said that the malingerer tended to caricature the disease and the hysteric to copy it. The effects of pain might be far-reaching; the reaction to trigeminal neuralgia might be so intense that suicide resulted. Causalgia was a serious and refractory cause of pain. Referred pain in a finger or toe that had been amputated might be a prominent symptom.

Some Illustrative Cases.

It had been held in *Cooper* v. *The Caledonian Railway*, that a plaintiff who was in a carriage the door of which swung violently back so that he thought there had been a collision, and had suffered alarm, headache, and nervous shock, had a cause of action against the company. Shock necessarily played a part, because it lowered the powers of mental resistance and perhaps increased the ease with which impulses were radiated through the cord.

Practical joking might be a cause of action, as in the case of *Williamson* v. *Downton*, 1897. Defendant told plaintiff that he had been instructed to tell her that her husband had met with a serious accident. The result was a violent shock resulting in pains, headache, vomiting, and many weeks' severe indisposition. It had been held here that though there was no injuria, yet an action had been committed which infringed the legal right to personal safety and had in fact caused physical harm.

In *Steel* v. *Behlan*, 1910, plaintiff, a charwoman, had been wounded by a needle which had become embedded in her hand. An operation for its removal had been followed by a contraction of the deep structures of the palm. Her chief complaint had been pain running up the hand into the left shoulder. Her employers had contended that her condition was due to nervousness in an unreasonable degree and not to any alteration of structure. The judge had been satisfied that she was not malingering, but that her inability to use her hand had induced in her a firm belief that she could not use it owing to the continued presence of the needle. The final judgment had been based on the conclusion that she had been unreasonable in not having exercised or worked her hand in a manner which would have prevented the condition of things which had then existed. Since the award the patient had had an operation for cancer of the breast on the same side as the pain in the arm. This case illustrated three important points: hysterical pain might be present; the patient must conduct her life in such a way as to give her a reasonable chance of improvement; and there might be an organic cause for the pain.

The plaintiff always had the benefit of the doubt, but must show a real desire to return to his employment.

Penal and Criminal Aspects of Pain.

The doctor might be called on to decide whether a prisoner could stand a flogging; any advanced organic disease would be a contra-indication. He might be asked during the punishment if the man's health was likely to suffer from its completion; severe hæmorrhage in the case of a hæmophiliac or signs of physical collapse would be the signal to stop. German jurists had paid much attention to acts performed during acute physical pain. English law recognised that the physical and mental pain of childbirth conduced to a state of mind calling for special treatment if a criminal act were committed. There was such a thing as pain delirium, and certain pains led to a disturbance of consciousness and mentality. Sadists and masochists found their way into the courts from time to time, and must be regarded as insane or as people who should be secluded apart from the general community.

Discussion.

Dr. A. S. WOODWARK said that he had never been able to find a satisfactory answer to the lawyer's question whether pain was or was not present. Any medico-legal statement on pain should be based on three factors: the history should prove clearly that there was pain and that it was due to the accident; the position and distribution of the pain complained of must be consistent with the history; and thirdly, no other cause for the pain must be apparent. Beyond that it was necessary to fall back on the veracity of the witness; if a man said he had a pain nothing could disprove it. Fortunately, it was not for the medical man to give any opinion upon this factor. With our feeble definition of pain and inadequate methods of proving it, all must depend on veracity.

Mr. ZACHARY COPE said that it was impossible to examine a patient properly in the law courts. He could recall many patients who had complained of pain with no apparent cause, but as the weeks and months had gone by some good cause had become apparent. Disease of the cerebrum was one of the commonest causes of pain; mental pain was a very real thing.

Mr. W. G. EARENGEY said that the lawyer's difficulty was not only the veracity of the witness, but also the question of whether a medical man had had sufficient opportunity of studying the case and whether on that account his opinion ought to be accepted. Pain in itself was not ground for compensation; all that a workman was entitled to was compensation for incapacity. In the ordinary common law action for negligence, pain was important because compensation was given in a lump sum and the plaintiff could not sue for an injury appearing later. At one time the law had said that there could be no damages for shock, but later a woman in the street who thought her child had been hurt by a negligently driven vehicle had been allowed damages. Not everybody, however, could recover damages for shock, the reason being that the wrong-doer was only deemed to contemplate the natural consequences of his wrong, and could not be held to believe that everyone in the street was going to suffer shock as the result of his negligence.

BUXTON MEDICAL RESEARCH SOCIETY.

A MEETING of this Society was held in the Devonshire Hospital on March 16th, when Dr. CRIGHTON BRAMWELL gave an address on the

TREATMENT OF AURICULAR FIBRILLATION.

He said that in many cases of circulatory insufficiency, although the heart is known to have been damaged in childhood or early youth as the result of rheumatic infection, and there is a valvular lesion of long standing, the more urgent symptoms which bring the patient to seek medical advice are of comparatively recent origin. The onset of heart failure in such cases is often attributable to an attack of bronchitis or to some special physical effort, and careful inquiry reveals that it coincided with a radical change in the cardiac mechanism—namely, the appearance of auricular fibrillation. In the great majority of cases fibrillation can be recognised without instrumental aid; the persistence of the irregularity when the heart is quickened by exercise or other means is the most reliable guide to its presence. It is in those untreated cases of fibrillation in which the heart-rate is slow that the clinical diagnosis is apt to present difficulty. This combination suggests either a badly damaged myocardium or the presence of some active toxic factor such as dental sepsis. The increased ventricular rate which accompanies fibrillation is by itself sufficient to account for the incidence of heart failure. Many beats are so premature that the ventricles are almost empty at the time of systole; such contractions are unproductive, since little or no blood is expelled from the heart and no pulse-wave reaches the periphery. By suppressing these premature beats the amount of work the heart has to perform is diminished, while the resultant prolongation of diastole improves the coronary circulation, and by allowing sufficient time for the ventricle to fill between the beats tends to abolish the "pulse deficit."

In the treatment of heart failure the first consideration is to curtail the heart's liabilities by reducing metabolism to a minimum. This is achieved by making the patient comfortable, and if necessary giving morphia to abolish restlessness, to relieve dyspnœa, and to ensure sleep. On the credit side of the account the aim should be to increase the cardiac output by slowing the heart with digitalis. In urgent cases massive doses should be given, in accordance with the method suggested by Eggleston, and provided the patient has not previously been taking any drug of the digitalis group, and an interval of six hours is allowed to elapse between successive doses, the method is perfectly safe, being, in the lecturer's opinion, preferable to the use of intravenous strophanthin. When the heart failure is less acute one drachm per diem of the tincture, or the equivalent dose of the infusion or the powdered leaves will meet the case. If toxic symptoms supervene, and this is especially liable to occur when the fibrillation is associated with advanced myocardial disease, the drug should be discontinued for the time being. The most important of such symptoms are nausea, headache, vomiting, oliguria, bigeminal heart action, and certain other less common types of arrhythmia. In this connexion it is important to distinguish the vomiting due to congestion of the gastric mucous membrane from that produced by an overdose of digitalis, and to remember that in febrile patients a heart-rate of 90 or 100 is comparable to one of 60 or 70 in afebrile subjects. Since about 20 minims of the tincture is eliminated from the body in 24 hours, small doses of digitalis may be given over long periods of time without producing cumulative effects. For oral administration strophanthus is less reliable than digitalis on account of the fact that its absorption from the alimentary tract is much more variable, a dose which produces little or no effect in one patient proving toxic for another.

Quinidine differs in its action from digitalis since it actually stops the fibrillation and restores normal rhythm in about 50 per cent. of the cases treated. Unfortunately it is only in a much smaller number that the normal rhythm is maintained, and one of the causes of relapse is the persistence of the toxæmia which originally induced the condition. In a series of temporarily successful cases belonging to the rheumatic group in which Dr. Bramwell had followed up the after-histories, 50 per cent. sooner or later reverted to fibrillation. Similarly when fibrillation is associated with gross myocardial fibrotic changes it is unreasonable to expect the same benefit from quinidine therapy as in those cases where the abnormal rhythm is of recent onset and the myocardium is relatively healthy. On the other hand, in those thyrotoxic cases where fibrillation still persists after the other symptoms have been relieved by a subtotal thyroidectomy, quinidine therapy is seen at its

best. In time the normal rhythm is restored and there is not the same tendency to relapse. It is difficult to assess with certainty the risks of quinidine therapy, for the special catastrophes for which it is blamed—namely, cerebral embolism, and sudden death, resulting from ventricular fibrillation—are liable to occur in any old-standing case of auricular fibrillation even if quinidine has never been used.

EDINBURGH OBSTETRICAL SOCIETY.

Ovulation and the Menstrual Cycle.

A meeting of this Society was held on March 13th, Dr. Haig Ferguson, the President, in the chair. Dr. Wilfred Shaw, after describing the histological changes that occur in the Graafian follicle during the process of ripening, went on to speak of the method used to determine the time relations between ovulation and menstruation. It consisted, he said, in the accurate histological examination of both ovaries of women with normal menstrual cycles. In these cases the dates of the last menstrual period and the day of the cycle when the specimens were obtained were known. It was found that recently ruptured follicles and proliferating corpora lutea could be demonstrated only after the sixteenth day of the cycle—the first day of the menstrual period being taken as the first day of the cycle. Until the thirteenth day of the cycle only retrogressing corpora lutea were found, although in cases corresponding to the post-menstrual phase ripening follicles were also present. The conclusions to be drawn were that ovulation took place between the thirteenth and sixteenth days of the menstrual cycle; that it occurred in healthy women constantly without gross variations in time, and that it occurred rhythmically once a month. Further indirect evidence in support of this view could be obtained by observing the earliest time in the cycle when premenstrual changes appeared in the endometrium, for there was good evidence to show that these premenstrual changes were produced by the corpus luteum. Further ovulation was inhibited by the corpus luteum derived from the follicle which first ruptured, and the rest of the ripening follicles in the ovaries underwent atresia, ultimately giving rise to the interstitial cells. Occasionally—in about 5 per cent. of cases—two follicles ruptured simultaneously, and two corpora lutea were found in the ovaries. If both ova were fertilised binovular twins resulted. Ovulation did not occur before puberty or after the menopause, said Dr. Shaw, for at these times no corpora lutea could be demonstrated in the ovaries. During pregnancy ovulation was inhibited, although ripening of the follicle proceeded normally; again, during lactation there was amenorrhœa because no corpora lutea were produced. If menstruation was regarded as due to the disintegration of a premenstrual endometrium, it could be differentiated from abnormal uterine hæmorrhage, and with this definition it followed that menstruation was invariably preceded by ovulation. Menstruation did not always follow ovulation; examples of this were seen in the case of pregnancy and in the condition described as corpus luteum persistens. Fertilisation probably took place only after the fourteenth day, but coitus might prove fruitful before this time, as spermatozoa might survive in the female generative tract for some time after it. Whether coitus could be fertile after the fourteenth day depended upon the survival-period of the ovum after ovulation, and in human beings there was very little evidence to show what this period was. It seemed, however, that the least fertile part of the cycle was the late premenstrual phase. There was evidence to show that the amenorrhœa met with in advanced stages of diseases such as Graves's disease, diabetes, and dementia præcox was due to an inhibition of ovulation. With large doses of X rays and radium ripening of the follicle was inhibited; with smaller doses ovulation was inhibited.

Reviews and Notices of Books.

Tonic Hardening of the Colon.

By T. Stacey Wilson, M.D., B.Sc., F.R.C.P. London: Humphrey Milford, Oxford University Press. 1927. Pp. 210. 8s. 6d.

In Dr. Wilson's experience the majority of his out-patient dyspeptic cases showed a condition of the colon characterised by tenderness, hardening, and increase of diameter on palpation. He regards the colon as subject to static and contractile muscular activity; when the former is above normal increased contraction is required to overcome the increased resistance. "This increase in the muscular activity of the colon," to use his own words, "would mean an exaggeration of the various reflex phenomena which result from the normal activity of the digestive organs." The symptoms so produced vary from abdominal pain to mental depression and include many diverse conditions. Treatment consists in lessening the abnormal tonic activity by means of intestinal antiseptics and a non-irritating diet, and in reducing the excitability of the reflex nervous mechanism by antispasmodics, especially hyoscyamus. The general health is attended to, and symptomatic treatment given for such troubles as abdominal pain, physical lassitude, and mental inertia. A non-stimulating diet is used if constipation coexists. The results obtained by Dr. Wilson on these lines have been excellent, with the exception of one case which terminated in suicide; but even in this case the author takes the view that with perseverance the illness would have ended in recovery.

Such is Dr. Wilson's thesis and his exposition is interesting, although he hardly makes it clear to the reader that tonic hardening of the colon is the main cause of the symptoms described. He speaks for instance, in one place (p. 33) of an abnormal excess of the stimulant which gives rise to tonic hardening, and in another (p. 36) of a neurasthenic condition, due to one of the less easily recognised causes of nerve strain, as the starting-point of the hardening. Treatment of the underlying condition would be the natural course if such is the case, and Dr. Wilson's own records support this. Many of his cases showed a neurasthenic tendency, and the obvious improvement may have been due to the general rather than the special treatment. This possibility will occur to the mind when faced with the aphorism (p. 192): "In every case of neurasthenia examine the colon for hardness and tenderness. If present, then colon treatment will, in all probability relieve and possibly cure the patient's symptoms." Undue emphasis seems to be laid on tonic hardening where some more important condition is present which may account for the symptoms. Thus a case is described (p. 101) where symptoms disappeared when the colon was treated, but reappeared soon after, the condition finally proving to be one of duodenal ulcer. The author himself comments that an alimentary X ray at the start would have been wiser.

The mode of causation suggested by Dr. Wilson for the tender hard colon is ingenious and well described. The wall of the colon is subject to two opposing types of muscular activity, the one static, the other contractile. Excess of the static function calls for increased activity of the contractile fibres to overcome the increased resistance. This increase in the muscular activity of the colon would mean an exaggeration of the various reflex phenomena which result from the normal activity of the digestive organs. As regards treatment, intestinal antiseptics and antispasmodics are admittedly of value in such cases, but just as the condition of the colic musculature is only one factor, perhaps a minor one, in the general pathological condition, so it seems likely that the author has not fairly estimated the

value of his skilful management of the cases on general lines.

The book is a thoughtful and stimulating production, it contains a capital table of contents, and the format leaves nothing to be desired.

DICTIONARY OF BACTERIOLOGICAL EQUIVALENTS.

French-English, German-English, Italian-English, Spanish-English. By WILLIAM PARTRIDGE, F.I.C., Joint Public Analyst for the County of Dorset and the Boroughs of Poole and Penzance. London: Baillière, Tindall and Cox. 1927. Pp. 141. 10*s*. 6*d*.

THIS book represents an attempt to supply the deficiencies of the ordinary dictionaries in so far as the laboratory worker is concerned. The conception is a good one and it has been ably executed by the author; the result, however, is not quite so satisfying as might have been expected. This is due to the fact that in wrestling with a foreign tongue it is not the words more particularly concerned with the subject which hold up the English reader; it is those in between which present the real difficulty. It is fairly obvious that a "cellule géante" is a giant cell and a shrewd guess may elicit that "conservant le Gram" indicates that an organism is Gram-positive. "Kohlensäure" presents greater difficulties, but even an ordinary dictionary is able to expose the curious gap in a language that has only one word for carbon and coal. While it must be admitted, from a cursory survey of this work, that it contains many words, the meaning of which is fairly clear without recourse to a special dictionary, none the less it is a scholarly effort and will undoubtedly prove of use to those who have no ready access to special dictionaries of the languages in which they are following up a subject.

TWINS AND ORPHANS.

By ALEX. H. WINGFIELD, B.A.Sc., Ph.D. London and Toronto: J. M. Dent and Sons, Ltd. 1928. Pp. 127. 10*s*. 6*d*.

THIS little monograph, a thesis submitted for the degree of Ph.D., is another attempt of a statistical nature to estimate the relative importance of heredity and environment in their effect on mental as distinct from physical well-being. Can racial differences be eliminated by education? Can any system of education create or even increase intelligence, or does it only provide material on which intelligence may play? To what extent are the wide differences in ability due to inheritance or to opportunity and environment? These and other questions will only receive answers when we are able to determine to what extent intelligence is inherited. The data on which the study is based relate to 102 pairs of twins and a shorter series of 29 orphans reared for varying periods under similar environment. The author finds that there is an increasing degree of resemblance in general intelligence among human beings with increase in the degree of genetic relationship among them; in other words, that general intelligence is an inherited trait. No greater degree of resemblance is found in those traits upon which the school concentrates its training than in general intelligence, which is not directly trained at school. Environment is developmental, therefore, not creative. The basic factor in learning being native intelligence, the problem is then to provide for each child a type of education based not so much, or not at all, upon chronological age, but rather upon what his or her native ability demands, and at the same time to retain the advantages, economic and educational, of group instruction. The method of grouping individuals on the basis of *mental* maturity and submitting each group to different school curricula has already been adopted in certain cities, and it will be interesting when comparative results of the two systems of education become available. While the general strength of the arguments contained in the book must be admitted, it is very doubtful if the author's estimation of the effect of environment from the correlation found by random pairing of orphans under similar (or any) environment is of much value. A short account of the cellular basis of heredity and the effect of environment on the inherited bodily structure, together with a full summary of the previous literature on the subject form the opening chapters of a very readable account of an interesting and important study.

A TREATISE ON TUMOURS.

Third edition. By JAMES EWING, A.M., M.D., Sc.D., Professor of Pathology at Cornell University Medical School, New York City; Pathologist to the Memorial Hospital. London and Philadelphia: W. B. Saunders Company. 1928. Pp. 1127. 63*s*.

Prof. Ewing's book is so generally recognised as the standard work on the subject that it is only necessary to chronicle the publication of this, the third edition, and to indicate how it differs from its predecessors. The chapter on tumours of bones has been entirely rewritten on the basis of information obtained largely from the Codman Registry of Bone Sarcoma, and this difficult subject has been considerably clarified. The classification of mammary cancer has been simplified, and the section on brain tumours has been revised. Throughout the book there are many minor alterations and additions, and there are 60 new illustrations. Although the individuality of the author is apparent on every page, the work as a whole deals so exhaustively with the subject that it will scarcely appeal to the student who requires more condensed and dogmatic teaching. But no one who is interested in tumours from anything but the examination point of view can afford to omit Prof. Ewing's book from his library, and one of its most valuable features is that all the references have been verified.

ORIENTAL HERBALS.

The Divine Origin of the Craft of the Herbalist. By Sir ERNEST WALLIS BUDGE, M.A., Litt.D., F.S.A. London: Society of Herbalists. 1928. P. 96. 5*s*.

EVERYTHING written by Sir Wallis Budge is thoroughly interesting, his knowledge being immense and his skill in imparting it being proportional. During the past 40 years a great deal has been found out about the forms and contents of oriental herbals, and this pamphlet introduces us to the oldest oriental herbals from the point of view of the archæologist. The little book is illustrated appositely by reproductions of excerpts from MSS. or tablets in the possession of the British Museum, where Sir Wallis Budge was at one time keeper of the Egyptian and Assyrian antiquities.

THE MICROSCOPY OF DRINKING WATER.

By G. C. WHIPPLE. Fourth edition revised by G. M. FAIR and M. C. WHIPPLE. London: Chapman and Hall. 1927. With 19 coloured and 7 plain plates, 123 text figures. Pp. 586. 35*s*.

THE late Prof. Whipple published the first edition of this book in 1899, and in successive editions it has been a standard authority ever since on the microscopic life (excluding bacteria) of waters with a sanitary interest. It has stimulated inquiry, and so much fresh material has accumulated in recent years that the present edition has been to a large extent rewritten. Algæ are, of course, the most important topic; mechanically and chemically they can deeply vex the sanitary engineer. Protozoa, rotifers, and polyzoa are also dealt with. Part I. (447 pages) takes up the collection and examination of organisms, their environment, the conditions which determine their prevalence, and how they can be kept in check by copper sulphate and other methods; it contains a great mass of interesting information, largely drawn from the personal experience of the authors. In Part II. the common organisms are

classified and described, and many keys are given to help in identification. It is necessarily only a summary, and does not attempt to get beyond genera; ample references are given to the specialised literature which precise work will often need. The illustrative figures are not as good as they should be nowadays; perhaps it will be possible to prepare a new set for the fresh edition into which so admirable a guide will doubtless pass.

JOURNALS.

BRITISH JOURNAL OF OPHTHALMOLOGY.—In the issue for January, 1928, R. R. James gives the result of his historical researches on Roger Bacon, without pretending to be an authority on the subject. He gives quotations showing that Bacon understood the magnifying properties of convex lenses and their practical use for old persons and those with weak eyes. It is interesting that he had to rely on the support of the then Pope against the opposition of his Francisian superiors for getting his writings transcribed.—S. Taylor Harris contributes notes on a case of aneurysm of the anterior cerebral artery causing compression of the optic nerves and chiasma, and E. Wolff suggests an anatomical explanation of the comparative frequency with which the sixth cranial nerve is affected in cases of increased intracranial pressure. Under the dura mater it runs almost vertically up the back of the apex of the petrous temporal bone. It is at the sharp upper border, where it bends forwards almost at a right angle, that it is liable to compression when there is increase of intracranial pressure.—Alex. MacRae, of Newcastle-on-Tyne, describes an operation which he has found very successful for ectropion of the upper lid. At least 40 different methods have been devised for the relief of this condition. The one here described is that of Dr. Webster, ophthalmic surgeon to the American College at Beyrout. Its principles are the division of the tarsal plate from the conjunctival surface, as in Burow's operation, and the insertion into the gap of a graft taken from the inner surface of the lip, without sutures. A similar method, but with sutures, has been described by W. O. Maher.[1] —David Hardie, of Aberdeen, records a case of myasthenia gravis in which the only symptoms were double ptosis and (when the eyes were opened) diplopia. The result of a successful Hess operation on one eye was greatly to relieve the patient's depression without revealing a diplopia which would have troubled him had both eyes been operated on.—J. G. F. Heal records a case of serious hæmorrhage from the conjunctiva of an infant, following excessive instillation of nitrate of silver.

In the February issue Dr. Adalbert Fuchs, of Vienna, writes a second paper on pseudo-glaucoma, the first having appeared in the *American Journal of Ophthalmology* in 1924. He gives notes and coloured illustrations of three cases. The first one was a true glaucomatous excavation of the disc coexisting with a congenital pit of a portion of it, the tension being normal. The other two were cases of congenital malformation of the optic disc simulating glaucoma. The three diagnostic points on which he relies to distinguish false from true glaucomatous discs, where only one eye is affected, are: (1) the larger size of the disc, compared to that of the fellow eye, in pseudo-glaucoma; (2) the veiling of the vessels at the foot of the excavation by semi-transparent neuroglia in pseudo-glaucoma; and (3) the aspect of the halo which in pseudo-glaucoma is irregular and often pigmented. The foregoing has reference to chronic glaucoma. He has also something to say of a case simulating acute glaucoma, but really due to angiectasis of the eyeball.—E. E. Henderson and R. R. James give notes of a peculiar case of glaucoma in an eye with a large physiological cup. This was observed to have become pathological 18 months after being passed as normal, while the tension which previously had been normal became raised. A trephining operation failed to stop the symptoms altogether. The second eye was normal.—Dr. C. D. Verryp, of Leiden, and Dr. K. T. A. Halbertsma, of Delft, record two cases of Parinaud's conjunctivitis, a somewhat rare affection. Bacteriological examination failed to show any causative micro-organism, and they consider it very improbable that the tubercle bacillus should be responsible for the disease.—R. C. Davenport, in a paper giving the after-results of cataract extraction, has analysed the Moorfields cases for the seven years, 1919–1925—642 in all. The end-results were: Vision of 6/12 or better, 68·7 per cent.; 6/60 or better, 19·7 per cent.; failures—i.e., less than 6/60, blind eyes and excisions, 11·9 per cent. It is only fair to say that the notable proportion of failures was accounted for in over half the cases by pre-existing lesions. Of the three types of operation now commonly performed—simple extractions, extractions with peripheral iridectomy, and those with complete iridectomy, the first two produced a higher proportion of good and very good results than the third. On the other hand, the surgeons who still practice complete iridectomy can point to a distinctly lower rate of iris prolapse. On the whole, it is noteworthy that Davenport's analysis shows very similar results to that of Devereux Marshall, who did the same work for the years 1889–1893.[2] The chief differences are the introduction of the modern method of peripheral iridectomy and the much greater frequency with which secondary needling operations are now performed than they were in Marshall's time. Then the percentage of cases was only 26·5. Now it is 62·4. We may add that Davenport's figures do not include a number of cases which were operated on by Barraquer's method during the years 1923 and 1924, and which have been separately analysed.[3]

The March number is largely devoted to M. D. Vernon's paper on the recording of ocular movements (see p. 664).—Dr. J. Wood, of Cape Town, reports a rare case of melanosis of the iris and new formation of a hyaline membrane on its surface. The appearances were so ambiguous that it was deemed safer to excise the eye, but no actual proof of malignancy was revealed by microscopical section.—E. Treacher Collins adds some remarks on the case.—The important report of the Council of British Ophthalmologists on Ophthalmia Neonatorum was commented on in our columns last week (p. 612).

Reports and Analytical Records.

CADBURY'S DAIRY MILK CHOCOLATE.

(MANUFACTURED AT THE GARDEN VILLAGE, BOURNVILLE, ENGLAND.)

WHEN analysed the following results were obtained:—

Moisture	1·00 per cent.
Ash	1·68 ,,
Fat	35·30 ,,
Protein, chiefly casein	7·87 ,,
Cane sugar	39·70 ,,
Milk sugar (lactose hydrate)	9·00 ,,
Other cocoa constituents	5·45 ,,

A consideration of these figures supports the conclusion that this milk chocolate contains at least one-quarter of its weight of milk solids, with their full proportion of fat. There is also present about 40 per cent. of cane sugar, together with sufficient cocoa butter and cocoa to constitute the chocolate as prepared. The additional food value secured by the presence of this high proportion of milk solids will be obvious to those interested in dietetic values, while the smoothness and palatability of the product will appeal to the consumer.

THE LANCET.

LONDON: SATURDAY, MARCH 31, 1928.

THE NAMES OF BACTERIA.

THOSE whose pleasure or duty it is to read bacteriological literature know very well that they who beget it live up to LINNÆUS's motto "Nulla dies sine linea." And they are beginning to appreciate the truth of another saying of his—"Nomina si nescis perit et cognitio rerum." At the moment there is no doubt that bacteriological nomenclature is in a mess which may be more or less intelligible to those who live in the subject and habitually talk in its jargon, but which is certainly a substantial obstacle to anyone coming in from outside to try to find out what bacteriology has to contribute to general biology (or, indeed, any extraneous subject) and to those medical men whose contact with bacteriological diagnosis is fitful and occasional. For practical purposes the difficult question of the broad classification of bacteria into families and orders and tribes can fortunately be neglected; and attention may be concentrated on genera and species. There is general agreement that LINNÆUS's binomial (perhaps with an extension into a trinomial) system has proved very satisfactory in botany and zoology for the past 150 years, and any attempt to systematise the names of bacteria naturally takes that plan as its model. Thus "*Bacillus typhosus*" is really as familiar as "the typhoid bacillus," and where such names are in common use no one has felt any more difficulty in the bilingual terminology than do the botanists to whom "Durmast Oak" and "Quercus sessiliflora" are interchangeable names. But there are many organisms which have been left stranded so to speak—the pneumococcus, the meningococcus, Gaertner's bacillus, Morgan's bacillus, for example, and no one has dared to lay impious hands on Pasteur's "vibrion septique." To the expert there is no difficulty, but the experts perhaps have not realised as soon as they might that there is nothing to tell the common man that the meningococcus is closely allied to the gonococcus, that Gaertner's bacillus and *Bacillus enteritidis* are the same thing, and that he must recognise the bacillus of gas gangrene as *Bacillus enteritidis sporogenes*, Welch's bacillus, *B. aerogenes capsulatus*, *B. welchii* and *B. perfringens* with a parallel variation in the generic names. Small wonder is it that attempts are being made to get some order and tidiness into this arrangement.

The Society of American Bacteriologists has interested itself in bacteriological classification for some time, and under its auspices two important books have appeared—Prof. R. E. BUCHANAN's "General Systematic Bacteriology" (1925), which deals with the history and definition of genera and larger groups, and the second edition of Dr. D. H. BERGEY's "Manual of Determinative Bacteriology" (1925), which is a catalogue after the manner of the "Systema naturæ." In trying to decide which is the "right" name of an organism, these authors have naturally tried to follow the law of priority which has grown up as a corollary to the Linnean system, and is probably about as good a principle to follow as any other. Some principle, of course, there must be; the choice cannot be left to the individual fancy of each author of a systematic list. The application of the law of priority is at least as difficult in the bacteria as it is in other groups; the older descriptions cannot always be identified with a current organism, and what were species when their first name was given have since become genera. But it is by no means impossible to make sound progress along these lines and there are not many very radical changes in Dr. BERGEY's list: *Micrococcus prodigiosus* becomes *Serratia marcescens*, *B. pyocyaneus* is now *Pseudomonas aeruginosa*, but the alterations which are proposed are fewer than might have been expected. They are not popular among bacteriologists any more than LINNÆUS's most necessary work was looked on with favour by great experimental naturalists like RÉAUMUR, who cared nothing for the identity and names of the animals he observed and experimented with. And in the fervour for systematisation and binomialisation some rather absurd things have been done; we hardly suppose that *Flemingillus* and *Robertsonillus* will ever be adopted as generic names for certain anaerobes even at St. Mary's Hospital and the Lister Institute. The transition from the old muddle to the new order is bound to be slow and to some extent painful. We welcome therefore particularly a reasonable half-way house in the form of a classified list of the more important pathogenic bacteria which appears in the current number of the *Bulletin of Hygiene*, and which gives the binomial and English titles by which the various organisms will in future be known in that publication. This should be very helpful and will, we hope, do something to persuade bacteriologists that a definite, consistent, and coherent nomenclature has become a real necessity. Its fabrication requires a good deal of work and, which is admittedly rare among bacteriologists, a scholarly knowledge of the history of their subject. An interest in the matter would be a very proper activity for the staff of the National Collection of Type Cultures. And in the end, no doubt, if we follow LINNÆUS's advice, we shall, like him, be able to kneel down on the ground and thank God for making the world so beautiful.

To some people such a goal seems impossible because bacteria are so obviously variable and mutable. This is a misconception of the position. Species among the higher animals and plants are no less real groups since we learned of evolution and found that any natural species is a mixture which may be dissected genetically into quite separate forms. Bacterial species appear to be just about as valid; they differ only because their exceptional rate of multiplication runs their time-scale together, and in consequence, in days or weeks we can see things happen which in ordinary animals and plants are spread over years and centuries and æons. Allowing for the time factor, bacteria will prove as amenable as mammals to any sincere attempt to classify and name them.

A JURY UPON NEGLIGENCE.

AFTER a hearing which began on March 13th and ended on March 21st, a special jury found for the defendants in an action brought by Mr. HENRY STROUD, of Sydenham, against Messrs. BATES, BATES and WILSON, medical practitioners, of St. Albans. The case deserves particular attention because in its conduct the difficulty experienced by juries, when deciding what constitutes negligence in a medical case, is well illustrated. The case shows, also, the importance to the patient of an X ray examination in many circumstances where a fracture can be diagnosed, and in all circumstances where it is suspected. The defence societies regard the procedure as an essential weapon for the

rebuttal of charges of malpraxis, and this should be remembered by the members of these bodies.

Mr. STROUD claimed damages for alleged unskilful treatment in attendance after a motor-cycle accident. The defendants denied that they were unskilful; they further pleaded that, if there had been a wrong diagnosis from which the plaintiff had suffered injury, it was due to a refusal on his part to submit himself to an X ray examination until three months after the accident. The plaintiff's case was that he had a motor-cycling accident on March 7th, 1926, in which the upper part of his right femur was fractured. He said that, when first examined by Dr. WILSON (a member of the defendant partnership), he was told that his muscles were bruised and his leg tendons strained, and that he was treated up till some time in June for strain and not for a fracture. Twelve weeks after the accident an X ray photograph was taken; it showed a fracture of the femur, a fracture which had not united. As the result of this delay in treatment, said the plaintiff, he would be a helpless cripple for the rest of his life, his only hope of cure being a serious and dangerous operation (by grafting on to the bone), if he were advised to submit to it. The case for the defendants involved a flat contradiction of parts of the plaintiff's story. Dr. WILSON said that, on his initial examination, he found Mr. STROUD had a dislocated collar-bone, but he saw no evidence of any other serious injury; he advised him, however, to go into hospital on the next day for an X ray examination. Mr. STROUD, according to Dr. WILSON, declined to go into a hospital and insisted on being treated at his lodgings. On making a fuller investigation next day Dr. WILSON found the patient complaining of considerable pain in his legs; there was bruising, discoloration, and swelling in the hips and lower part of the back. He found no crepitus, but was suspicious of several fractures in the neighbourhood of the pelvis, spine, sacrum, and femur. According to Dr. WILSON'S evidence in court, he again advised the plaintiff to go into hospital and have an X ray examination, and the plaintiff again emphatically refused. Without such examination there were no definite signs of a fracture; massage was ordered to remove the pain and stiffness in the back and hip, but massage was subsequently discontinued owing to the pain it caused. Ultimately Dr. WILSON reopened the matter of the X ray examination; Mr. STROUD at last consented and the fracture was thereby discovered. The main issue in the case was whether Dr. WILSON had advised an X ray examination from the beginning. Doctors can only advise; they cannot compel; if a patient declines to follow advice, the doctor can do nothing but suggest the next best course. The finding of the jury for the defendant doctors is to be taken as an acceptance of Dr. WILSON'S statement, or at any rate (since the burden of proof lay on the plaintiff) a refusal to accept Mr. STROUD'S version.

The jury was absent for four hours and to its verdict for the defendants added the following singular rider: "We are of opinion that Dr. WILSON should have protected himself by calling in another doctor and repeating in his presence the advice that Mr. STROUD should go to hospital and submit to Rontgen rays." There is no chance of cross-examining a jury, so we can only speculate upon the meaning of this pronouncement. It cannot mean that Dr. WILSON should have called in a second opinion, for the second doctor was to be called in not to advise the plaintiff, but to hear Dr. WILSON repeat his advice—not for Mr. STROUD'S benefit, but for Dr. WILSON'S protection. Did the jury mean that Dr. WILSON, foreseeing litigation and the conflict of evidence, should prudently have equipped himself with corroboration? If so, why call in a second doctor? Why not a justice of the peace or a commissioner for oaths? The prudent practitioner, it seems, will in future diagnose by affidavit and prescribe by statutory declaration. After a week of harassing anxiety Dr. WILSON succeeded in rebutting the allegation of unskilfulness, but the proceedings have done nothing to contradict Lord Justice SCRUTTON'S dictum (mentioned in our columns last week) that a jury is an unsatisfactory tribunal for determining issues of skill or negligence.

TUBERCULOSIS ON TYNESIDE.

THE latest addition to the series of tracts [1] for the times issued by the Newcastle Bureau of Social Research is devoted to the prevalence of tuberculosis in the towns on the Tyne banks. In this densely populated district, where badly built and overcrowded houses stand on ill-drained clay, where sunshine is obscured by smoke, where unemployment is prevalent and poverty rife, the conditions for the spread of tuberculosis are ideal. Between 1920 and 1925 Gateshead and South Shields had a death-rate from this cause unequalled by that of any of the English county boroughs. The town of Jarrow had a record even worse than that of its larger neighbours. Though the average death-rate (per 1000 of the population) for all forms of tuberculosis in England and Wales during this period had fallen to 1·083, the corresponding figure for the Tyneside industrial towns was 1·599. Jarrow had a death-rate from pulmonary tuberculosis more than twice that of the average for the urban districts of England and Wales. Whilst the death-rate in Newcastle has been halved in the last 40 years, that of Jarrow remains what it was a generation ago. These figures are profoundly disquieting. They are of vital concern not only to the citizens of Tyneside, but to the whole country, for the factors that have produced a high incidence in Jarrow are likely to produce a similar result elsewhere. The cause of the high death-rate in the Tyneside towns has been variously attributed to malnutrition, to poverty, to overcrowding, to the nature of the subsoil. Probably all these factors are concerned, but there is no reason to doubt that here, as elsewhere, a vigorous campaign against tuberculosis would have reduced its incidence and mortality. The pamphlet explains how any scheme to combat the disease must have reference to the tuberculous persons as the source of infection and to the conditions which make for tuberculosis. Chief emphasis is laid on the latter. Thus the two most important points for Tyneside to consider at the present time are the segregation of persons suffering from advanced tuberculosis and the vigorous prosecution of schemes for building new and reconditioning old houses. The Tyneside Papers merit the attention of all who are interested in social questions. The present paper is a model of what a pamphlet of this kind should be. The chief facts of the situation are clearly stated and, despite conditions calculated to rouse indignation, the writing is marked by restraint. The suggestions made for reform are practical and supported by experience obtained in other areas. Sixty years have passed since John Ruskin wrote his letters to dwellers by Weare and Tyne, and the Papers recall the advice of the Victorian prophet. The words may be less eloquent, but the message is the same—that without clear thinking there can be no helpful action, and that even political power is of no avail unless it is directed by knowledge. We may trust that now the Tyneside communities know the facts they will be moved to take concerted action.

Annotations.

"Ne quid nimis."

DAIRY FARMING IN THE NETHERLANDS AND DENMARK.

In view of the agitation which has been going on for the prohibition of the importation of condensed skimmed milk, the recently issued report[1] of the Commission appointed by the Ministry of Health to inquire into the conditions of production of milk in the Netherlands and Denmark will be widely read by all interested in British dairy farming. The members of the Commission were Dr. J. M. Hamill, a medical officer of the Ministry; Mr. T. A. Hole, a milk inspector of the Ministry; and Prof. J. Mackintosh, of Reading University. The report shows that in the principal dairying provinces of the Netherlands, Friesland and Groningen, the farmers' coöperative movement is very highly developed, and controls its own creameries and factories for the condensing and drying of milk. The actual dairy products turned out vary according to which happens to be the most remunerative at any given time. In the southern provinces, in which the large towns are situated, there are still some private firms who buy milk from the farmers and compete with the farmers' coöperative societies, and owing to the demand for milk in the towns, condensing becomes more of a subsidiary seasonal activity for surplus milk.

The Commissioners were impressed with the excellence of the Dutch cowsheds which, unlike those in England, have been especially designed for dairy cattle. The artificial lighting of the sheds, whether by natural gas or electricity, is particularly good, and considerable attention is given to the grooming of the cattle. There is little manipulation of the milk at the farms and the milking equipment is consequently simple. Within a very short time of production the milk is being pasteurised at the creamery, so that cooling by the farmer is unnecessary and no special milk room is required. The cows are out in the fields from May to November and milked outside during those months. The payment received by the farmer is based upon the fat content of the milk and the results of certain tests, and the requirements for good quality milk appear to be more stringently enforced by the coöperative societies than by private firms. In preparing skimmed condensed milk the cream is first separated, sugar is added, and the mixture is pasteurised at about 90° C. The Commission found that every precaution for cleanliness was adopted at the condensing factories visited. The purity of the milk-supply in the Netherlands is controlled by a Royal decree, dated June, 1925, and the country is divided into 20 districts, each provided with its staff of inspectors and an efficient laboratory with a staff of chemists and bacteriologists. A district laboratory may examine as many as from 20,000 to 30,000 samples of milk in the year. The farmers' coöperative societies also have their organisations for securing satisfactory milk, and the Commission were very favourably impressed with the efficiency attained by these coöperative organisations in controlling the purity of the milk and the health of the cows. The conclusion, as regards the Netherlands, arrived at by the Commission is that the differences which exist in the production of milk and its conversion into dairy products, or in the regulations which control it, and the manner in which they are administered in this country and in the Netherlands are not sufficiently marked to warrant any differentiation on grounds of danger to health between dairy produce made in England and similar produce made in the Netherlands, and that our regulations do not place any significant burden upon the English farmer which is not already borne by the farmer in the Netherlands.

In Denmark the Commission found that the coöperative movement deals with about three-quarters of the total milk produced, but that the coöperative creameries are chiefly occupied in making butter and that the skimmed milk is chiefly used for the feeding of pigs. The manufacture of condensed milk is on a much smaller scale and, as a result, the Netherlands export to us nearly four times as much skimmed condensed milk and nearly five times as much sweetened full-cream condensed milk as Denmark. The general arrangements otherwise found in Denmark were similar to those in Holland. The Danish cowsheds were even superior to the Dutch. In both cases the excellence of the buildings is not due to regulations, but apparently to recognition of the needs of the case. As regards Governmental control of the milk-supply, a distinction is made in Denmark between milk which is to be used as milk and milk which is to be manufactured into milk products. The Commission conclude: "Notwithstanding the relative paucity of regulations dealing with milk intended for manufacturing purposes in Denmark, we do not think that the milk delivered at condenseries in Denmark differs in any notable respect from the average milk produced in England." It will be seen, therefore, that this report affords no justification for any interference with the importation of condensed skimmed milk on the grounds of danger to health or production by unfair competition. The lesson to be learnt from the report is rather that the further development of the coöperative movement in this country would lead both to improvement in the quality of the milk and to better financial results for the farmer.

[1] H.M. Stationery Office. 1928. 6*d*.

EARLY DIAGNOSIS AND CARE OF MEASLES.

As one of our regular correspondents in the United States remarks in another column, the care of measles in young children is attracting close attention there. In a paper[1] read last November before the New York Academy of Medicine Dr. P. M. Stimson states that measles may often be predicted with some confidence before the appearance of Koplik's spots. "Following the onset of fever," he says, "a slight puffiness of the lower eyelids may be noticeable, and there may also be found a fairly definite line of congestion across each lower lid, about at the margin of the tarsal cartilage and perhaps a third of the way from the lid margin to the fornix." He adds that "in ten children in whom I have observed what I thought was a typical measles line of this sort in the eye and have prognosticated the disease at this stage, it subsequently became manifest in eight." The so-called measles line must be quite marked to be suggestive; its duration as a line is generally brief, the injection spreading in a day or so to involve the entire peripheral conjunctiva and later the palpebral conjunctiva; whilst it should be noted that children with catarrhal conditions other than measles may show a linear conjunctivitis just inside the blepharal margin of the lower lid. One would like to know, but Dr. Stimson does not state, the number of cases suffering from other catarrhal conditions in which he looked for a linear congestion, and the number of measles cases quoted is small. But if his observations are confirmed the sign may prove of considerable value in early diagnosis of the disease. In considering the other signs, Dr. Stimson sums up the features of the invasion stage as follows. First comes fever, followed 12 hours later by puffiness of the lower eyelid and perhaps the measles line, together with the first evidence of the exanthem on the fauces. Then in another 12 hours comes catarrh, followed in a further 12 hours by Koplik's spots. Finally, when 36 more hours have elapsed, the rash appears. During the whole invasion period there is a certain amount of headache and malaise. Most observers will find it difficult to agree that it is usual for measles to be so precise in the presentation of its invasion symptoms as this suggests. While-

[1] Jour. Amer. Med. Assoc., March 3rd.

a rise of temperature is usually the first evidence in the invasion stage, it is common enough for catarrhal symptoms to come on at the same time, and they may precede the rise of temperature. Again, Koplik's spots often appear two and three days before the eruption and, in rare cases, may even be the first sign of the disease. The variation is such as to make it of doubtful advantage to set out the symptoms in chronological order. Though strong suspicion may arise in any given case, no definite diagnosis of measles can be made before the appearance of Koplik's spots, unless the so-called measles line proves pathognomonic. As regards management, Dr. Stimson puts forward a plea for the individual isolation of every individual sufferer from measles. In support of it he says that almost innumerable instances can be quoted of otitis media and broncho-pneumonia spreading in a measles ward or through a family group of measles patients. With the individual isolation of all patients at the Willard Parker Hospital, the incidence of secondary infections is said to have dropped very markedly, and with this drop has come a notable fall in the mortality from the disease. The first step towards individual isolation of the patients at this hospital was taken in 1923 to prevent a repetition of the crowding of 1922, when New York City experienced the heaviest measles year of the twentieth century. In further support of his argument Dr. Stimson says that these secondary infections at times seem almost as contagious as the primary measles. Whilst all will agree with him that individual isolation is the ideal mode of dealing with this, or indeed with any important infectious disease, the measure is costly in application. In London there are at the present moment 1500 or more cases of measles in the M.A.B. hospitals. It is not the general experience, moreover, that the complications of measles tend to be almost as infectious as the disease itself. Under adverse conditions patients with broncho-pneumonia are, of course, very apt to infect others in juxta-position, but this does not happen in wards, where the floor-space per patient is sufficient and where there is adequate ventilation by way of the windows. To a great extent the home conditions control the incidence of broncho-pneumonia in measles, and the worse these conditions are the greater the frequency of that complication.

VENTILATION AND HEALTH.

ATTEMPTS to improve the ventilation of buildings have not always been very happy. A case in point [1] is revealed by an American investigation of sickness (especially respiratory) experienced by school-children during the winter of 1926–27. Two groups were chosen. The first consisted of 1232 children attending three recently built, two-storey, plenum-ventilated schools. In this system of ventilation fresh air, after being warmed, is forced into the room by fans through openings 8 or 10 ft. up the wall, and is then drawn out by exhaust fans from near the floor; the radiators warming the air are under thermostatic control. The second group consisted of 794 school-children attending three naturally ventilated, furnace-heated schools, built not less than 40 years ago, with no other source of air-supply than the furnace-ducts and open windows. They represented the crudest type of construction now to be found in the field of school heating and ventilation. Unfortunately no third group, attending open-air schools, was used; but in New York State such schools could hardly be kept open during the winter months. Careful observations were made of the temperature of the rooms in all the schools throughout the period selected, and the data collected, after every possible allowance had been made for differences in the ages and racial origin of the children, showed that those attending the three modern schools had an average absence due to respiratory affections nearly double that of the children at the three old schools. Cases of respiratory disease noted by the teachers among the children who attended school were found to be twice as numerous in the modern as in the old schools. The conclusion drawn from this careful piece of research, which is to be extended, is that a high air flow produced by plenum fans (particularly when combined with high room temperatures) tends to be associated with an excessive incidence of minor respiratory diseases among school-children. Such a conclusion, if correct, is of real value. In this country also there are many different types of heating and ventilation; can we not borrow an idea from the United States and study their influence upon school-children? Judging from the American investigation, the school and not the home is responsible for some at least of the ills discovered among the children by our school medical service, and there seems to be an opportunity here for collaboration between the Board of Education and the expert investigators of the Medical Research Council.

[1] The School Ventilation Studies of the New York Commission on Ventilation. By T. J. Duffield. American School Board Journal, January, 1928. Effects of Mechanical and Natural Ventilation on the Health of School-children. By T. J. Duffield. Journal of the American Society of Heating and Ventilating Engineers, 1928.

MOVEMENTS OF THE EYE IN READING.

A PRINCIPAL part of the March number of the *British Journal of Ophthalmology* is devoted to two articles by M. D. Vernon, of Cambridge, on the methods of recording ocular movements and on movements of the eyes in reading. It was thought at one time that in reading the eyes move backwards and forwards smoothly and continuously, and that perception of the words took place during the movement. It is now known that the eyes move forwards in a series of jerks, and for the last thirty years various observers have investigated the character of these jerks and fixation pauses. The matter is not unconnected with the question of fatigue, and it is satisfactory for readers of THE LANCET to be told that the lines of print least fatiguing to the eye-muscles are those not more than 8·5 cm. in length. As might be expected, the number of fixation pauses varies very much with the individual, his age and ease of reading. The time occupied by the inter-fixation movements is very short compared with that occupied by the fixation pauses; it is the number and duration of the latter which make the difference between a slow and a fast reader. Very slight movements of the eyes also occur during fixation. The eye is never completely at rest, but fluctuates about a central position, moving through an angle of the order of one minute.

A JOURNALISTIC CENTENARY.

ON Feb. 23rd last the *Boston Medical and Surgical Journal* celebrated its centenary, and died, to rise, like the phœnix, as the first number of the *New England Journal of Medicine*, though it may be noted that on the title-page, against the figure "Number 1" are placed the words "Volume 198." This first (or 101st) issue contains the interesting story of the origin and development of the *Boston Medical and Surgical Journal*, illustrated with portraits of John Collins Warren (1778–1856), the founder, and of John Ware (1795–1864), who a little later joined the enterprise—the two had been associated 16 years previously in the issue of a medical journal which had died. A third portrait shows Dr. G. B. Shattuck, who became the editor in 1881, holding the position until 1912, the longest and most successful administration of the journal. There are also pictures of the front covers of the *New England Journal of Medicine and Surgery*, Vol. I., 1812—this is the short-lived predecessor—and of the *Boston Medical and Surgical Journal*, Vol. I. (February, 1828–February, 1829), with its first page, dated Feb. 19th, 1828; other illustrations show the front page of the same journal, Vol. VIII., No. 1, Wednesday, Feb. 13th, 1833, and the front page of Vol. XXXV.,

No. 16, Wednesday, Nov. 18th, 1846, the various specimens showing the changes in style of page and printing. There is also a cover of the *Medical Intelligencer*, Vol. I., 1823–24, the first weekly medical paper ever printed in America conducted by Dr. Jerome V. C. Smith, and published by John Cotton, of Boston, proving that the claim of THE LANCET to be the first medical paper to be issued weekly can be a matter only of days, one way or the other. An informing paper on medical journalism is supplied by Dr. Morris Fishbein, the editor of the *Journal of the American Medical Association*. He gives, with dates, the titles of many medical periodicals published at the beginning of the nineteenth century, and calls attention to the fact that the *Medical Intelligencer* of Boston, founded by Dr. J. V. C. Smith, appeared in the same year as THE LANCET—namely, 1823—but he does not assign priority to either. It is interesting to note that the influence of British journalism was so strong among medical journals for some years that a vigorous move was made to give American character to American publications. A committee was appointed in 1848, presided over by Oliver Wendell Holmes, who the previous year had been elected professor of anatomy and physiology in the University of Harvard, and this body reported that the definite differences in the American constitution and the definite presence in the New World of diseases different from those of the Old World showed that there was a national field for the American scientist to cultivate. How fruitful a field may be gathered from the fact that 30 years later Holmes himself deplored the multiplicity of medical publications in America and elsewhere, while figures supplied by Dr. Fishbein show that the output must be steadily increasing. We welcome the hundredth birthday of our well-known contemporary, whose editorial chair has been filled always by competent journalists, and in whose columns the contributions of many American doctors of international repute have appeared.

INTRACRANIAL HÆMORRHAGE OF THE NEW-BORN.

THE association of asphyxia neonatorum with intracranial hæmorrhage is so firmly established by experience as to be beyond all question. Arising from this association there was at one time an assumption that the hæmorrhage is caused by the asphyxia—an idea put forward by Little in his original paper, and more dogmatically by subsequent observers. No conclusive evidence, clinical or pathological, has been adduced in support of this causal relationship, and of late years the tendency has been to reverse the sequence, and regard neonatal asphyxia as the result of intracranial hæmorrhage, the cause of both being some form of trauma. In Prof. H. Ehrenfest's valuable monograph (1922) this attitude was adopted, with the reservation that asphyxia acts as a predisposing and contributory factor, because engorged veins are more prone to rupture and extravasate blood. A year or two ago Dr. F. R. Ford,[1] whilst expressing his opinion that clinically there is no reason to suppose that asphyxia is an important ætiological factor, pointed out that the question can never be solved on clinical grounds, because of the impossibility of excluding traumatic lesions. In a further investigation,[2] therefore, he has invoked experimental methods, and has attempted to ascertain whether asphyxia per se may leave permanent cerebral damage. For this purpose a number of kittens were asphyxiated by various methods and to varying degrees. In all those which could be resuscitated recovery was complete, and in none of those which died in asphyxia were any definite cerebral lesions to be found; it appeared that the heart-beat was stopped by anoxæmia before any lesion was produced in the brain. Incidentally it may be noted that a comparison of the effects of coal-gas and of pure carbon monoxide suggested that the cerebral lesions which the former produces are due to some unknown poison, and have no relation to carbon monoxide anoxæmia.

Dr. B. P. Burpee,[3] in a recent review of the ætiology and treatment of natal hæmorrhage, adopts a like attitude toward asphyxia, but gives special consideration to the hæmorrhagic diathesis. He has rarely found that the bleeding and coagulation times are increased, and so regards the tendency to hæmorrhage as no more than a contributory factor. He is, however, convinced that intramuscular injection of whole blood is essential in the management of these cases. Dr. Burpee's account of the treatment which should be instituted brings into prominence the divergence of opinion on this question. Besides injection of blood, he advises immediate lumbar puncture. This may be repeated "every 6, 12, or 24 hours according to the symptoms"; its object is to reduce intracranial pressure, and it is done irrespective of whether the fluid obtained is clear or hæmorrhagic. It may be that in this recommendation Dr. Burpee is influenced by his opinion that intracerebral hæmorrhage is rare—an opinion not universally shared. His conviction that the advantages of lumbar puncture greatly outweight the disadvantages, and that reduction of intracranial pressure is always beneficial, are in striking contrast to the conclusions reached by Prof. C. Grulee [4] who contends that removal of fluid and lowering of intracranial pressure are likely to aggravate a hæmorrhage which has not been completely arrested. It is, of course, difficult to ascertain the exact origin of blood obtained by lumbar puncture in the new-born. It may come from a vein in the canal which has been pricked by the needle.

THE COMMONWEALTH FUND.

FEW people in this country have heard of Fargo, North Dakota, but it is the principal subject of the ninth annual report of the Commonwealth Fund.[5] Six years ago it was a prosperous small community, with no unusual health deficiencies, which had never become awake to the need and value of systematic public health service. The functions of its health department were divided between a part-time health officer, a sanitary inspector, a State employee in a State laboratory, a school nurse, and a Red Cross nurse. The Commonwealth Fund chose it as the centre for a demonstration of how municipal health affairs should be conducted. This year Fargo will be served by a full-time health officer, a school dentist, six public health nurses, a director of school health education, a part-time school physician, and two clerical workers. The fundamental purpose of the demonstration was to secure a wider acceptance of maternal and child health services as an essential part of a complete public health programme, and a graph shows vividly the improvement in sanitation, control of infectious disease, and maternal and child health during the years of the demonstration. As a result of the final year's work the children in the five white elementary schools attained 100 per cent. correction of dental defects. Stress was laid on building up and preserving the health of the so-called normal child. The experience of the demonstration appears to point strongly to the conclusion that it is possible to set up, in a relatively short time, an attitude on the part of school teachers which gives health a radically different status in the minds of growing children. The children in turn teach their parents. "When," says the report, "children voluntarily troop to the doctor for long-range protection against communicable disease an attitude of far-reaching importance has been fostered." It must be confessed that to British minds this seems dangerously like a sacrifice of the *mens sana* to the *corpus sanum*. Not that the healthy mind is forgotten

[5] Address: One East 57th Street, New York.

by the Commonwealth workers. An institute for child guidance has been opened, with a large staff, five of whom are English students. A mental hygiene programme is to be organised in England, and in preparation for this fellowships and observation trips have been arranged for a number of English visitors. The first group of British graduates has now returned to this country and two more annual groups are at work in America. Children accused of every kind of misconduct and delinquency have been received at the Bureau and a large proportion of them have been successfully treated. The information service on child guidance and mental hygiene has answered hundreds of inquiries from all parts of the world, and has published text-books and pamphlets. Educational and legal research and the child welfare work are being continued, and the granting of scholarships in Austria has been extended to workers in strategic positions throughout the country. It will be admitted by all that the satisfactory methods of one country are not necessarily the best for another, and the wisdom of the Commonwealth directors is shown in the fact that no attempt has been made in Austria to introduce American health methods. It will be interesting to see what emerges from the friendly conflict of Commonwealth ideals with British practice when the campaign over here is in full swing.

SANITATION OF THE DEAD.

FOLLOWING a leading article on the disposal of the dead in THE LANCET of Feb. 11th (p. 297), a number of interesting letters have appeared in our correspondence columns. The problem is one which has always confronted mankind, and it is so closely bound up with religious beliefs and social customs, that it is difficult to approach it with a dispassionate mind. Even in an age of comparative hygienic enlightenment the mere suggestion of any interference between the bereaved relatives and their dead would give pain and offence to many. Nevertheless, the methods of the disposal of the dead as carried out in this country are far from satisfactory. Prolonged contact of the dead with the living is bad from every point of view, and it would be of benefit to everyone if at the earliest possible moment after death the corpse could be removed from the dwelling-house to a mortuary or undertaker's parlour. During the subsequent interval which must necessarily elapse before burial or cremation, decomposition could be prevented by the use of a refrigerating plant, or, as is so common in America, by the practice of embalming. Instead of embalming, it has been suggested that sanitation of the corpse should be carried out by the injection of formalin or some other antiseptic solution into the main vessels, but it is a question whether this would be desirable or even effective. There is very little evidence that in this country disease is ever propagated by the presence of a corpse under ordinary conditions, and it is doubtful if the injection of antiseptic solutions into the great vessels would render a corpse bacteriologically sterile. Such an injection would effectively allay the bogy of premature burial, but this fear can be dealt with by other means. And there is the real danger that embalming or antiseptic injections might interfere with a subsequent examination of the body should this be considered necessary. One of the great objections to cremation is the possibility this procedure affords of the concealment of crime, and for this reason special precautions must be taken before any body can be cremated. It is conceivable that injections might have a similar drawback, and for this reason, if for no other, they would have to be rigidly controlled. Unless and until cremation becomes general, anything which tends to delay the corruption of a corpse and its resolution into its constituent elements is to be deprecated. The rapid removal of the body from the dwelling-house to some recognised place would fulfil all requirements, and if this could be combined with a post-mortem examination by an accredited individual, the fear of premature burial would disappear for ever, the concealment of homicide would become more difficult, and medical science would be advanced.

AGE-DISTRIBUTION OF BLINDNESS.

IN a recent annotation on the Welfare of the Blind (March 10th, p. 507) a statement in the Seventh Report of the Advisory Committee was quoted to the effect that 0·5 per cent. of the present blind population —i.e., 258 out of 46,822—are under five years of age, and this statement was regarded as inconsistent with another statement that 17·4 per cent. of the present blind population became blind within the first year of their life. We understand from Dr. F. N. Kay Menzies, medical officer of health for the County of London, that there is actually nothing inconsistent in these two statements. The 17·4 per cent. covers persons of all ages who were born blind or became blind in the first year of life. Assuming that infantile blindness could be wholly prevented for the next five years, while it is true that there would be no persons included in the 0–5 age group, there would, of course, be large numbers of older blind persons who had in the past become blind between the ages of 0–5. It is probably prior to the Ophthalmia Neonatorum Order of 1910 that about one-third of the blind had become blind during the first year of life. Of the 46,822 existing blind persons, 43,340 are over 21 years of age, so that to-day there are living large numbers of blind persons who probably became blind through ophthalmia. This accounts for the apparently high percentage of 17·4 referred to above. It is interesting to note that when the first census of the blind was made in 1919, 21·4 per cent. were recorded as having become blind during the first year of their life.

IDENTIFICATION OF BABIES IN HOSPITAL.

IN most English maternity hospitals the risk of mixing up babies is slight, but some of the larger institutions in the United States have found it necessary to adopt elaborate systems of identification to prevent a confusion, the legal and psychological results of which may be disastrous. Dr. J. B. de Lee, in the *Journal of the American Medical Association* for Jan. 21st, gave an interesting account of the scheme in use in the Chicago Lying-in-Hospital, where 15 babies are sometimes born within eight hours, and where three named Clark have been born on the same day. No single precaution was found trustworthy. In an avalanche like the above, 69 can be read as 96; J. Jones's plaster can get on J. James's back; wrist tapes can fall off or be illegible; the physician may announce the sex wrong or the nurse may make a clerical error. All these and other accidents have often occurred, and the Chicago system, though it may seem irksome, is, according to Dr. de Lee, infallible. The labour ward has a time-book in which are written the names of the parturient and the father. The assisting nurse sets down the times of rupture and delivery, the sex and weight of the child, obstetric particulars, the names of the physician and "scrubbing" nurse, and the number which is to be attached to the baby's navel and wrist. When the baby is born, the cord is tied with a sterile tape bearing an aluminium tag with a number, which the physician calls aloud. Before the cord is cut, the clean nurse ties a tape bearing the same number round the baby's wrist, also speaking the number aloud, and hands a third tape to a bystander to fasten on the mother's wrist. The bystander repeats the number so that all can hear it, and the timekeeper enters it in the time-book. Any disagreement in the original numbers is thus immediately apparent, and the navel-wrist number is associated with the name in the book. A nurse now fills in a form printed on adhesive plaster and fixes it on the child's back; this form has the names, the sex and date of birth of the baby, and the navel-wrist number. At the same time the

office is notified by telephone of the child's sex, the words "son" or "daughter" being used to avoid phonetic confusion, and the hospital entry number is obtained and entered in the time-book and on the history-sheet. Only after this has been done may the child be removed from the labour ward. The child's footprints are now taken, one copy on the mother's labour record and one on a pink sheet which is given to the mother to keep; this sheet also bears, in addition to the other chief particulars, the ubiquitous navel-wrist number, which further appears on the crib-card when the child is sent to the nursery. The mother generally knows her baby before the cord with the navel tag falls off; if she does not, she still has the wrist number and back plaster to help her. The baby goes home wearing these two documents, which are often kept by the mother as souvenirs, together with the navel tag and pink sheet. In case of doubt, the evidence of these records taken together would be sufficient for any jury. Dr. de Lee anxiously invites criticism, but we do not think many readers will be able to find a loophole in his organisation.

IODINE DEFICIENCY AND GOITRE.

MUCH scientific war has been waged around the problem of endemic goitre, and at least six theories have been put forward to account for its occurrence. Prof. D. W. Carmalt-Jones's paper before the Section of Medicine of the Royal Society of Medicine on Tuesday last was a lucid and convincing account of the work in New Zealand, where, as he said, the first thing that strikes the eye of a stranger in the street is the preponderance of goitres. It has been stated that Maoris do not suffer from the complaint, but although this is true of the coastal Maoris, those who have been driven inland have had in their language a word for goitre as long as tradition goes back. In a recent survey of 300 of them, 18 per cent. were found to have enlarged thyroids. The prevalence amongst Europeans has been noticed since 1888, and 1500 men were refused for the Army out of some 130,000 examined when conscription came in during the war. Whatever the environmental factor may be, it does not act uniformly all over the islands, for the incidence among schoolchildren is 16 per cent. in Auckland and 28 per cent. in Wellington, rising to 56 per cent. around Canterbury. With a selective regional incidence like this research workers had something to go on. Fæcal contamination in the drinking-water was excluded by the fact that Christchurch has quite as good a standard of water-supply as Auckland; radio-activity of the water from artesian wells was put out of court by the fact that the incidence was 60 per cent. in an area where the water runs freely in the open. The incidence was high in places where the water-supply was entirely taken from the roofs, and lowest of all in a limestone district, so the suggestion that salts in the water had some ætiological significance could be disregarded. Diet is strikingly uniform all over the country, said Dr. Carmalt-Jones, and could not be held responsible for a condition with such variations in degree. Geological considerations put forward in Europe could not now hold for New Zealand, but as soon as Hercus examined samples of the soil of the different districts for iodine-content, a striking parallelism between low soil iodine and high goitre-rate was manifest. The preventive treatment, therefore, was to add iodine to the food, and early failures in this direction had been found to be due to overdosage. The amount required was minute, four parts per million being the proportion allowed by the Health Department. The problem of toxic goitre, Dr. Carmalt-Jones pointed out, is much more complicated, and an overdose of iodide in simple goitre may well produce serious toxic symptoms. In the subsequent discussion Dr. Scott Williamson said that the endemic goitre of India is quite certainly not the endemic goitre of New Zealand. McCarrison had found an abundance of iodine in the soil and the vegetable food, and his work was as convincing as that of the New Zealand workers. Dutch investigators have made the interesting observation that those who are susceptible to toxic goitre in Holland are all immigrants, in the third generation, from Switzerland, whose ancestors were liable to simple goitre. Ancestral predisposition possibly plays a part in causing the condition, and, as Dr. Williamson said, there seems little doubt that simple goitre can arise from a number of causes. It may be that there are two quite different types, with different ætiology and different pathology. It is by careful work of the kind done in New Zealand that we shall reach more definite conclusions.

WE report elsewhere in this issue that the Senate of the University of London has appointed a committee to consider the situation arising out of the decision of certain London hospitals not to admit any more women students.

Dr. W. W. Jameson, medical officer of health and school medical officer for Hornsey, has been appointed to the University Chair of Public Health, tenable at the London School of Hygiene and Tropical Medicine. A report of the appointment appears in our news columns (p. 679).

THE death has occurred in Glasgow of Dr. George Stevenson Middleton, consulting physician to the Royal Hospital for Sick Children and the Royal Infirmary. Dr. Middleton, who was 75 years of age, was at one time President of the Association of Physicians of Great Britian and Ireland.

A DESCRIPTIVE account and catalogue of the exhibits in the Home Office Industrial Museum has been issued by H.M. Stationery Office (price 3*s.* 6*d.*). The Museum, which was opened in December last by the King and Queen, has the primary object of informing all who are connected with industry in the latest and best methods of promoting the safety and health of workers; it also affords in a compact and convenient form an object-lesson to medical practitioners and students of the medical side of industrial problems. The Museum has been well visited by many classes of inquirers since it was opened three months ago, and the handbook will serve as a guide to a well-spent visit, while many visitors will find it useful to refresh their memory from it with a view to paying further visits with more instructed minds. The promoters of the Museum intend to keep in touch with the authorities of similar museums abroad, using the interchange of information and ideas to make for progress in industrial hygiene on an international basis.

THE National Association for the Prevention of Tuberculosis has issued a fifth edition of its Handbook of Tuberculosis Schemes for Great Britain and Ireland. This useful compilation is in effect a tuberculosis directory of the various administrative areas in so far as mortality from tuberculosis and provision for its control and treatment are concerned. The information is obtained from trustworthy sources and has been brought carefully up to date. In the present edition data for the Channel Islands are included and the addresses of care committees and of health departments are given. Unfortunately, in many cases there is still no care committee to give an address of. Included in the Handbook are a couple of striking graphs giving the death-rates from tuberculosis in the year 1926 for the various administrative counties, from which the reader can at a glance pick out those in which effort has been apparently less successful. The Handbook will, we may trust, serve a purpose in exciting rivalry between county areas for a good place on these graphs. The price of the handbook is 7*s.* 6*d.* post free from the Association, whose address is for the present, 1, Gordon-square, London, W.C.1.

Modern Technique in Treatment.

A Series of Special Articles, contributed by invitation, on the Treatment of Medical and Surgical Conditions.

CCLXIX.—THE TREATMENT OF THE SEQUELS OF HEAD INJURY.

IT is not within the scope of this article to treat of all the manifold disorders that may follow injury to the head—conditions as divergent as the rare traumatic diabetes insipidus and the common facial palsy. Attention will therefore be confined to the more common sequels, and to those whose treatment may become a matter of urgency, even at a time remote from the day of injury.

Persistent Cerebral Contusion.

A rational treatment of persistent cerebral contusion can be based only upon a knowledge of its pathology, which we owe largely to Trotter.

Owing to the rigidity of the cranium the volume of the intracranial contents is constant. A limited swelling of the brain can be accommodated at the expense of the cerebrospinal fluid, but any further increase in size must lead to compression of neighbouring veins and capillaries. A localised cerebral contusion, such as is produced by a blow or a fall upon the head, is characterised by small hæmorrhages and extravasation of blood plasma from damaged vessels. In any other part of the body these products of injury would quickly be removed by way of the blood-vessels and lymphatics. Owing, however, to the unique position of the brain within the rigid skull, the œdema impedes the circulation in its neighbourhood and so prevents its own absorption. Consequently, the contusion may persist unchanged for months or years, giving rise to distressing symptoms of which the most prominent are paroxysmal headaches, often of great severity, attacks of giddiness, and mental disturbances, such as irritability, nervousness, and inability to concentrate. Treatment in such cases is directed to breaking the vicious circle upon which the persistence of the contusion depends and so permitting the absorption of the exudate.

Many cases of persistent cerebral contusion can be prevented if the injury, however slight, is adequately treated in the acute stage.* Treatment of the late cases is based upon the same principles. Rest in bed is the first essential and the patient should be forbidden to get up for any purpose. Sometimes the headaches, which are apt to be most severe in the early morning, can be prevented by the patient's learning to sleep sitting up with his head and shoulders supported upon pillows. Hypertonic saline solution is administered, preferably intravenously, the dose being 70 c.cm. of 15 per cent. sodium chloride solution, slowly injected. Several such injections may be given at intervals of four or five days if necessary. Alternatively, six ounces of a 25 per cent. solution of magnesium sulphate may be administered by the mouth or by the rectum once or twice a day, the patient's intake of fluids being restricted meanwhile; but in our experience the intravenous route is the most effective. The usual analgesic drugs may of course be used in addition, if necessary, for the relief of headache.

Cases of persistent cerebral contusion which fail to respond to treatment with hypertonic solutions require surgical interference. Inasmuch as there are usually no localising signs and the object of operation is to relieve a rise of intracranial pressure rather than to deal directly with a focal lesion, the operation of choice is a right subtemporal decompression. In the event of focal symptoms being present it is wise to do the subtemporal decompression on the affected side. If it is thought advisable to inspect the site of contusion an osteoplastic flap may be combined with the subtemporal decompression.

A new method of treatment for persistent cerebral contusion has recently been introduced by Wilder Penfield.[1] In a case presenting the classic symptoms of persistent cerebral contusion Penfield introduced air into the subarachnoid space in the lumbar region for the purpose of diagnostic radiographic studies. He found to his surprise that within a few days the patient was completely relieved of symptoms, and these did not recur in the ensuing five years. Subsequently he treated six other cases by injecting air in amounts up to 100 c.cm., with remarkable success. The air floats to the uppermost part of the subarachnoid space and can thus be manipulated, by arranging the position of the head, to the region where the headache is most intense. In this region pneumograms have frequently shown subarachnoid or subdural cystic collections. The explanation of the relief of the headaches is not yet clear, but the method appears to open up an important field in the pathology and treatment of post-traumatic headaches. The reader is referred to Penfield's paper for the technique of lumbar insufflation. We would point out that the method is still in its infancy and that it should only be used after most careful consideration and with all the precautions that a major surgical operation demands.

Traumatic Neurasthenia following Head Injuries.

By traumatic neurasthenia we understand a state of anxiety neurosis which occurs in the absence of, or outlasts recovery from, an organic lesion produced by an accident. It is especially prone to follow injuries of the head since the potential seriousness of head injury is well known to the laity. It rarely occurs if the injury be so severe that its disabling effect is undeniable and, as Buzzard says, it hardly ever develops unless the patient is able to fix the responsibility for his accident upon someone else. This statement, however, is liable to misinterpretation unless it is further analysed.

The treatment of traumatic neurasthenia depends entirely upon a sympathetic understanding of its ætiology. In order to make this clear it will be helpful to trace the development of the condition in the imaginary case of a head injury sustained by a workman in the course of his employment.

A labourer while at work is struck on the head by a falling object and sustains a moderately severe concussion from which in other circumstances he would have recovered in a few days. On receiving his injury he is taken to hospital, where he is told by the doctor that he has had a narrow escape from a fractured skull. From his friends, who comment on his ill appearance, he learns that his accident was due to the carelessness of a fellow workman. His employers acknowledge their responsibility to the extent of allowing him half-pay. As a wise precaution against sequelæ he is kept in bed for three weeks and on getting up he naturally feels weak. He now begins to fear that he will not be well enough to return to work for some time. In view of his family responsibilities this excites in him a natural anxiety which intensifies his feelings of weakness. On returning home he feels somewhat better, but owing to lack of exercise he is out of training for heavy manual work. He inquires if his firm can give him a light job and is told that this is impossible and that he must wait till he is quite well before resuming work. This intensifies his anxiety, for he fears that if he returns to work and breaks down he will have sacrificed his half-pay and his earnings will cease. If, on the other hand, he remains at home indefinitely he knows that sooner or later his compensation will come to an end. He has by this time developed a definite anxiety neurosis as a direct result of the situation in which he finds himself. It is unnecessary to trace the familiar story further in detail. Ultimately the man is medically examined on behalf of his employer and usually he is pronounced fit for work, and his compensation is withdrawn. He now embarks on litigation which further harasses him, threatening

* The treatment of head injuries in the acute stage was described in THE LANCET of March 17th and 24th.

[1] Penfield, Wilder: Surgery, Gynecology, and Obstetrics, December, 1927, p. 747; see also THE LANCET, 1927, ii., 1401.

increased expense if it fails and rendering any retreat from his claim morally impossible. Finally his case is decided and, strangely enough to the superficial observer, whether he wins or loses his suit he speedily recovers from his neurosis, thereby confirming the cynic in his opinion that traumatic neurasthenia is merely a mercenary form of malingering. This, however, is an unjustifiable conclusion. The decision of the case cuts the Gordian knot by throwing the patient back upon his own responsibility. He has no longer anything to lose by partial recovery, which therefore ceases to be in itself a source of anxiety to him, and he rapidly recovers completely.

It is evident that traumatic neurasthenia is in its later stages, especially when complicated by litigation, temporarily incurable. It is, however, eminently preventable and, when it first develops, quite amenable to treatment. In dealing with industrial accidents and accidents involving possible claims for compensation every care must be taken, consistent with adequate treatment of organic lesions, to avoid suggesting incapacity to the patient. As soon as he gets up his symptoms must be explained to him and if there is no organic lesion present he must be told that any weakness or giddiness he may feel are the natural results of confinement to bed and will soon pass off. Positive suggestions of speedy recovery must be made. At the earliest possible moment physical exercises should be begun for the double purpose of restoring the patient's capacity for manual labour and inducing a feeling of well-being, one of the most powerful psychological aids to recovery. Lastly, an early attempt should be made to obtain the sympathetic coöperation of the employer or foreman, who can do much to remove the fear of a breakdown following a resumption of work. Many cases of traumatic neurasthenia would never develop if the employer and workman could be made to see that their interests are identical and not, as they are too often from the first assumed to be, mutually antagonistic. Unfortunately, the doctor can do nothing to remove the ultimate source of anxiety, an industrial situation in which "light jobs" are almost unobtainable and the penalties of incapacity so severe.

The problem of dealing with traumatic neurasthenia following head injury is complicated by the fact that persistent cerebral contusion is an organic lesion of the brain produced by trauma, which is usually associated with no abnormal physical signs. Since this condition may cause definite symptoms of anxiety it may easily be diagnosed mistakenly as neurasthenia. It is important, therefore, to exclude persistent cerebral contusion before attributing symptoms following head injury to a neurosis.

As in other states of neurosis, the bromides are of value for the relief of symptoms in traumatic neurasthenia.

Traumatic Epilepsy.

Epileptiform convulsions following head injury may be either generalised or Jacksonian in character. Statistics derived from gunshot wounds of the head during the late war have shown that the proportion of cases developing epilepsy as a sequel is about 5 per cent., a figure which is remarkably constant in all countries. This fact suggests that the fits are not the result solely of the injury, but are probably the outcome of a predisposition to epilepsy, the trauma being only the precipitating cause—a point of importance in relation to treatment. The routine treatment of traumatic epilepsy should be medical, and conducted on the same lines as in the "idiopathic" disease. It is well to begin with potassium or sodium bromide, grs. 10 t.d.s., and to add luminal or luminal sodium, gr. ½ to gr. 1 t.d.s., if the fits are not controlled by bromides.

Operation should be considered in cases which fail to respond to medical treatment after a few months, for if it is to be undertaken it must not be delayed too long. If the presence of a focal lesion is indicated by the history, by radiographic signs, or by the focal character of the fits, exploration may be made at the appropriate site. In some cases benefit has followed excision of, or injection of alcohol into, a localised area of cortex. In view, however, of the probable presence of a constitutional factor in these cases too much must not be expected of such operations.

Subdural Hæmatoma.

There is a curious condition in which blood accumulates beneath or within the dura and only gives rise to symptoms weeks or even months after the initial injury. The blood is for the most part in form of clot and is enveloped in a distinct membrane. It forms a solid mass on the convexity of one or both hemispheres. The condition is frequently mistaken for intracranial tumour, for the initial injury may have been slight and the symptoms are those of slowly increasing intracranial pressure, including papill-œdema, with slight and variable focal signs. The clot should be removed by operation, and particular care must be taken to leave the field of operation dry, for post-operative hæmatoma is very liable to occur. The condition is so frequently bilateral that when once hæmatoma is disclosed over one cerebral hemisphere an exploratory puncture should be made on the other side and at the same operation for, as Trotter has shown, there is danger in delay.

Cystic collections of blood and cerebro-spinal fluid occasionally form beneath the dura as a result of injury and give rise to symptoms like those of subdural hæmatoma. They are treated in the same way.

HUGH CAIRNS, M.B., B.S. Adel., F.R.C.S. Eng.,
Assistant Surgeon to the London Hospital.

INFECTIOUS DISEASE IN ENGLAND AND WALES DURING THE WEEK ENDED MARCH 17TH, 1928.

Notifications.—The following cases of infectious disease were notified during the week:—Small-pox, 359 (last week 347); scarlet fever, 1607; diphtheria, 1205; enteric fever, 33; pneumonia, 1590; puerperal fever, 42; puerperal pyrexia, 115; cerebro-spinal fever, 11; acute poliomyelitis, 10; encephalitis lethargica, 22; dysentery, 9; ophthalmia neonatorum, 117. No case of cholera, plague, or typhus fever was notified during the week.

The cases of small-pox were notified from the following 20 counties:—London, 10 (Paddington 2, Wandsworth 8); Berks, 1; Derby, 15; Durham, 61; Lancaster, 21; Leicester, 1; Lincoln, Parts of Lindsey, 9; Middlesex, 11 (all except 1 from Heston and Isleworth); Norfolk, 1; Northumberland, 18; Nottingham, 18; Somerset, 2 (Bridgwater, Taunton); Stafford, 21; Suffolk West, 1; Warwick, 16; Yorks, North Riding, 4; West Riding, 90; Brecknock, 5; Glamorgan, 28; Monmouth, 26.

The number of patients in the Infectious Hospitals of the Metropolitan Asylums Board on March 20th-21st was as follows:—Small-pox, 8 (one of them being under observation); scarlet fever, 1596; diphtheria, 2508; enteric fever, 32; measles, 1523; whooping-cough, 143; puerperal fever, 10 (plus 7 babies); encephalitis lethargica, 70; "other diseases," 37. At St. Margaret's Hospital there were 13 cases of marasmus and 14 babies (plus 7 mothers) with ophthalmia neonatorum.

Deaths.—In the aggregate of great towns, including London, there was no death from small-pox, 2 (1) from enteric fever, 172 (97) from measles, 9 (2) from scarlet fever, 43 (11) from whooping-cough, 43 (9) from diphtheria, 54 (11) from diarrhœa and enteritis under two years, and 100 (15) from influenza. The figures in parentheses are those for London itself. The death from enteric fever outside London was reported from Birmingham. Of the 75 fatal cases of measles outside London, 13 were reported from Sheffield, 11 from Tottenham, 7 from Plymouth, 6 each from Bristol and Worcester, 5 from Manchester; while the figure in Glasgow for the same week was 14 (Dublin not reported). The number of stillbirths registered during the week was 301 in the great towns, including 61 in London.

IMMUNITY AND VITAMIN DEFICIENCY.

A REVIEW OF THE EVIDENCE.

THE idea that the immunity of the body is lowered by dietary deficiency is a very attractive one, and it is remarkable how little experimental evidence there is in support of it. In a paper read before the British Association at Leeds last year and published in our columns, W. Cramer [1] drew attention to the relation of national health to milk production and milk fat consumption. He referred to the best-known example of infection related to dietary deficiency, which is familiar to every dietetic worker who has dealt with rats—i.e., the occurrence of an acute or chronic lung disease in rats, which is associated with a deficiency of the antixerophthalmic vitamin, vitamin A. Lack of this vitamin seems to lead to a breakdown of the mucous membrane, by which, according to S. B. Wolbach and P. R. Howe,[2] a stratified keratinising epithelium is substituted for the normal one. The epithelium may then become infected at many points in both old and young rats. I. G. Macy and co-workers[3] noted otitis media, mastoid disease, and sublingual abscesses, besides the usual lung disease, and H. C. Sherman and F. L. McLeod[4] were extremely struck with the liability to broncho-pneumonia, induced in rats by a deficiency of vitamin A; they argued from the rat to the human being.

Effects of Dietetic Deficiency in Human Infants.

It remained for C. E. Bloch,[5] of Copenhagen, to trace the same condition in human infants. In his studies on children suffering from xerophthalmia, as a result of a diet deficient in vitamin A, he noted the liability of such children to catarrhal infections of the mucous membranes, particularly of the respiratory organs, and to infections of the urinary tract, with *Bacillus coli*. So serious were these infections that the child died if the diet were not changed. Olaf Blegvad [6] gives a set of these cases, in which, out of 60 fatal ones, where the cause of death was known, 46 were due to broncho-pneumonia. The dietary conditions studied in Denmark were, of course, extreme. It is hard to believe that broncho-pneumonia of infants can ordinarily be associated with a lack of vitamin A, but a mild degree of insufficiency might exist and manifest itself in no other way than by a lowering of immunity.

The Antirachitic Vitamin.

When we turn to the antirachitic vitamin we are on less sure ground. The Report to the Medical Research Council on Rickets in Vienna [7] (1923) records that respiratory infections, otorrhœa, and furunculosis were less common in a group of children receiving energetic antirachitic treatment than in a comparable group which were not receiving it, but the antirachitic treatment consisted chiefly in the administration of cod-liver oil, which is rich in vitamin A as well as in vitamin D, so that it is not possible to say which vitamin was responsible for the improved condition. W. Eichholz and H. Kreitmair [8] have lately investigated the effect of diets, rich and poor in vitamin D (irradiated ergosterol), on adult rats and mice. In a series of rats a spontaneous epidemic of paratyphoid occurred among the animals without vitamin D, while those receiving it were spared, but it was never found possible to repeat this observation. It was found that mortality from inoculation with a virulent strain of pneumococcus was decreased by administration of vitamin D and still further decreased when vitamin B, in yeast, was added as well. It is suggested that even among adult human beings vitamin D may have a beneficial effect in raising resistance in the winter when sunshine is scanty. The effect of vitamin D upon immunity is not regarded as a specific one, but one which is common to any form of dietary deficiency.

Inconclusive Experiments.

Every bit of human experience in the matter goes to show that lack of vitamin D facilitates the development of tuberculosis and that administration of vitamin D, as cod-liver oil, or provision for the body, of the opportunity to form vitamin D itself, by exposure to ultra-violet light from the sun or an artificial source cures it after it has developed. There is, however, remarkably little experimental confirmation of this. A leading article in the *Journal of the American Medical Association* (Feb. 4th, 1928) quotes investigations by Agnes H. Grant and co-workers,[9] who have induced tuberculosis in the otherwise very resistant albino rat by feeding it on a rachitic diet. They do not appear to have been troubled by inconsistency in their results, but S. S. Zilva and H. Schütze,[10] who carried out experiments of a similar type, found it very difficult to arrive at any clear-cut conclusion. In their summary they state that they found some evidence for saying that "a large excess of fat-soluble vitamins in the diet, as supplied by cod-liver oil, inhibits the formation in rats of these tuberculous tumours, but such evidence was by no means conclusive." They also found that the inclusion of large amounts of cod-liver oil in the diets of rats, or ultra-violet irradiation of the rats, produced a slight, but constant, leucocytosis. S. S. Zilva [11] had also previously investigated the influence of deficient nutrition, on the production of agglutinins, complement, and amboceptor. He used rats and guinea-pigs and studied deficiencies of the elements, Ca, Fe, K, Cl, P, and Na, of certain amino-acids, and of the antiscorbutic, antineuritic, and fat-soluble vitamins; restriction of total calories was also studied. It was found that a deficiency of phosphorus was the only one which had any effect in lowering the titre of agglutinins and amboceptor. Experiment has not, therefore, been able so far to throw much light on the problem, and we must be chiefly guided by empirical knowledge.

PUBLIC HEALTH OF SOUTH AFRICA.

THE annual report of the Department of Public Health of the Union of South Africa for the year ended June 30th, 1927,[1] bears close resemblance to its predecessors. Nothing remarkably new is found in its pages, but it is a faithful record of the activities of a rather small Government department, which, even if striking progress is absent, manifest steady improvement in many respects. The work of the department was again severely handicapped by the apparent unwillingness of the legislative assembly to put the Medical, Dental, and Pharmacy Bill on the statute book. This is a long overdue measure, and the same holds true in the case of the Food, Drugs, and Disinfectants Bill. The department also deplores its lack of power to deal with matters like general hospitals, district nursing, school medical inspection and cognate affairs. This is due to the Provincial Administrations having kept the control of these and many other matters too long in their own hands. Attention is drawn to the facilities which the Union Government offers to owners of sick cows, in contrast to the enormous difficulties surrounding the provision of medical aid for those living in remote localities. This does not refer to paupers, for whom the services of

[1] Pretoria: Government Printing and Stationery Office. Pp. 70. 2*s*. 6*d*.

district surgeons are available, but to the ordinary class of farmer. The cautious and gradual building up of a State-aided medical service, to be both preventive and curative, is suggested as a hopeful line of advance. The report makes good use of its opportunity to contradict the statements which have appeared in certain newspapers, that the whole population is a C 3 one. The European birth-rate reached 26·5, the European death-rate was as low as 10·15, the infantile mortality-rate was at 64·8; those are reassuring figures, and they show a steady improvement every year. The need for more knowledge of elementary health matters throughout the population is, however, still making itself felt. The department, it will be seen, keeps in touch with international health matters and epidemic intelligence through the channels nowadays available, and has its own intelligence system for inland use. But as regards local authorities, only nine of these have whole-time medical officers of health, and this seems to be worth attention.

The activities of the department include the usual inspections, and the publication and distribution of pamphlets on various health subjects. In future, conforming to the spirit of the time, more use will be made of the public press for such purposes. The sanitation and the water-supplies require a good deal of watching. The port health services have worked satisfactorily. Pending the necessary legislation little can be done to safeguard the public against adulteration of foodstuffs. The department controls the one and only tuberculosis sanatorium, another large hospital for venereal and infectious diseases, and not less than six leper institutions. The notifications of infectious diseases are admittedly too low, as many cases, especially among natives, are never seen by a medical man. It is specially mentioned that the very low figures for *ankylostomiasis* are explained by the dryness of most parts of the country. *Bilharziasis*, however, is rapidly spreading, and a reliable drug, which can be taken by mouth, is very urgently needed. The large outbreak of *dengue* on the Natal coast is apparently not expected to recur. There still is too large a prevalence of *enteric fever* in many centres. The position as regards *leprosy* is gradually improving, although the Government did not see fit to find funds for allowing proper research to be undertaken. That the Union of South Africa is now in the van of progress regarding leprosy is being universally recognised. *Malaria* is of importance for certain definite and generally sparsely populated areas only. A mosquito survey is being undertaken. *Plague* remains a source of danger. The total number of human deaths was only 56, but rodents are increasing in number in areas where they were scarce before, and plague infection of rodents is present over enormous areas. Much efficient work is being done on the eradication of rodents by means of gassing, poisoning, and burning. Urban and rural local authorities have been urged to enforce the rat-proofing regulations; appreciable progress has been made in this respect and the rat in many centres has been "built-out." Research work on *senecio disease* has found a way to prevent this insidious affection, which is conveyed by bread. The promptness with which a threatening outbreak of *small-pox* among the Asiatic and native population of Durban was stamped out by the department shows what can be achieved by a well-advised public health authority which has material, men, and knowledge at its disposal. The Government, however, still refuses to enforce the vaccination provisions of its own Public Health Act; it has stopped prosecutions of objectors, and as a result of this there is a rapid accumulation of unvaccinated persons. About *tuberculosis* no reliable figures can be given, but the need for investigation has been felt and a comprehensive scheme has been started. The position as regards *typhus fever* and *venereal diseases* is not clear. The department has also interested itself in the matter of house-building and public loans for that purpose.

Among other matters we have notes on the child welfare movement, which, under the patronage of Her Royal Highness Princess Alice, held a first congress, and both local authorities and the public show an increasing interest in such matters. There are special courses for a mothercraft certificate, and also for nursery nurses. For the importation and sale of opium and similar drugs Government regulations exist which were duly enforced, giving rise to a large number of prosecutions. Nearly 16,000 lb. of dagga were exported to London. The section on slaughtering and meat inspection shows the prevalence of measly meat and the difficulties arising therefrom which are as yet unsolved. The Union now possesses two Universities which provide a complete medical training; the number of medical students appears to be excessive. The report publishes a summary of the findings of a hospital survey committee, which are too elaborate for this brief abstract; reforms appear to be quite urgent, but no further move has been made. The report concludes with some remarks on hotels, public mortuaries, safety measures in mines, and prevention of seaside bathing accidents. Attention must finally be drawn to the beautiful coloured map showing the distribution of predominant veldt rodents and plague.

UNITED STATES OF AMERICA.

(FROM AN OCCASIONAL CORRESPONDENT.)

Mayor Thompson Rebuked.

THE whole public health world was indignant when the Mayor of Chicago dismissed from office the city health commissioner, Dr. Herman N. Bundesen, whose public health services are so well recognised that he was elected President of the American Public Health Association at its last annual convention. In place of Dr. Bundesen Mayor Thompson has appointed his personal physician, a man whose experience in public health work has not been tried out. Some of the most competent men in the health department have felt obliged to resign. Public health work in America has long been held back by the pernicious influence of politics. It has seemed lately that politicians were disposed to recognise the importance of tenure in office of civil servants. The action of Mayor Thompson has been a rude shock to rising hopes. A firmly worded editorial of protest has appeared in the *American Journal of Public Health* and an even more emphatic statement of protest has been issued by a group which is thoroughly representative of American sanitarians. "The action of the Mayor of Chicago," they say, "strikes a blow at the most fundamental principles of good government. It should meet with prompt and vigorous rebuke from all people of Chicago who care for the reputation of their city, and it should stimulate citizens everywhere to see that city charters are amended so as to make such interference with good health administration impossible in their own communities." The statement is signed by the following amongst others: the Professors of Public Health in the Universities of Johns Hopkins, Columbia, and Yale; the Presidents of Cornell and Leland Stanford Universities; and the Directors of the Schools of Public Health at Pennsylvania and Johns Hopkins Universities.

Reducing Mortality from Measles.

It is now just two years since the city of Syracuse, whose health department is coöperating with one of the health demonstrations of the Milbank Foundation, began its systematic attempt to meet the attack of the measles epidemic then due. They based their campaign on a recommendation first made by the late Dr. John Brownlee and subsequently reinforced by Dr. E. S. Godfrey [1] in this country. This plan is to concentrate the defence forces upon patients under three years of age, since at least 70 per cent. of deaths occur in this age-group. In order that early diagnosis which is so essential to successful treatment should be secured a publicity campaign was begun in good

[1] American Journal of Public Health, June, 1926.

time. The expected epidemic arrived, and the story of how it was met is well told by Drs. Ruhland and Silverman.[2] Ninety per cent. of the cases were diagnosed before the fifth day. This is a remarkable achievement. To it and to the use of convalescent serum must be attributed the drop in fatality for all cases under three years to 1·6 as compared with 5·1 in the previous (1923–24) epidemic. The fatality for the city as a whole is shown to be 43 per cent. below the normal fatality for American cities of its size. Dr. Stimson, of New York, has now drawn attention to an early eye sign—the appearance of a line of redness in the conjunctiva of the lower lid about one-third of the way from the lid margin to the fornix. This sign is found usually very soon after the onset of fever and is a valuable aid in early diagnosis. Dr. Stimson pleads also for early segregation, since he holds that mortality is due chiefly to secondary infections. It seems probable that earlier diagnosis secured by popular health education and suitable administrative measures may halve the present mortality. The closing of schools is from this point of view a hindrance rather than a help. Neither the schools nor the infant welfare centres were closed during the Syracuse epidemic of 1926–27.

"Audi alteram partem."

SOME OBSERVATIONS ON ASTHMA.

To the Editor of THE LANCET.

SIR,—In view of the interest which is at present being taken in asthma, I feel that a few observations on this distressing complaint will not be out of place. In using the term "asthma" I refer to bronchospasm and not to the other manifestations of this condition. Until recently asthma was generally considered to be a form of bronchitis, produced mainly by exposure, to be treated by expectorants and confinement to bed on a milk diet. The prespastic stage was not recognised.

Asthma, however, never occurs in a patient in whom certain recognisable conditions have not previously taken place. In the child the previous history is usually that of frequent attacks of bronchitis and sometimes of one of the fevers. The child is said to take cold easily, often has a running nose and, possibly, some eczematous patches. In older patients the first attack is very often subsequent to, and merging from, an attack of influenza. Urticaria and eczema are frequent prespastic features, the latter often to be found in the region of the sternum. None of these conditions is constant, but it is rare not to elicit one or more from the history.

The most constant feature that I find in asthma is constipation. This is a condition that at all costs must be corrected. Many years ago Dr. James Adam of Glasgow showed that asthma results from two causes: a toxæmia and a lesion in the respiratory tract. I have been treating patients along these lines for the last ten years with satisfactory results; with increasing experience one finds it possible to discover the origin of the toxæmia without undue delay, although much care and time is usually necessary. For the nasal factor the help of a skilled rhinologist may be required. At the same time wholesale nasal surgery is to be deprecated. It is common to find asthma patients who have had antrum operations, but whose asthma remains unchanged. Frequently in such cases attention to ethmoid infection clears up both the bronchospasm and the antral discharge. Antral infection commences usually in an unhealthy ethmoidal region and treatment of the one without the other will accomplish little towards the relief of the asthma. The object of the rhinologist should be to remove any pathological condition in the nose and all accessory sinuses with the minimum of destruction. Much can be achieved by antiseptic dressings, as suggested by Dr. J. I. Dowling, of Albany, N.Y., but thorough knowledge of the technique is necessary. For the remainder, careful search must be made for any septic focus that may be present, such as apical abscess, gall-bladder infection, or chronic appendicitis, and appropriate steps taken to correct any such condition that may be found.

To ascertain the immediate cause in the production of bronchospasm and remove it is not enough. To discover that a patient gets asthma when he sleeps on a feather pillow, or is exposed to a dust-laden atmosphere is creditable, but to advise him that his only hope is to avoid these things is simply running away from his enemy. I have had many patients who have been advised that to obtain relief they would have to leave this part of the country and live in the south. Such advice is admission of failure of treatment, besides being impossible to a man whose business or professional ties are in the immediate neighbourhood. By attention to diet, bodily hygiene, adequate exercise when advisable; to proper bowel, skin, and kidney elimination, together with consideration of the points I have mentioned above, one is enabled to treat asthma with confidence. For patients with intestinal toxæmia, who cannot tolerate plain paraffin, the addition of kaolin is beneficial.

The greatest difficulty is to secure adequate cooperation between doctor and parents or patient. It is particularly hard to get a mother to realise that outdoor exercise is really necessary to her ailing child. She wants to keep the youngster wrapped up by the fire if the weather is cold, while the doctor should want him to discard his cotton-wool and chase his "Fairy" cycle up and down the pavement for an hour or so a day. Patients, when they have been free of asthma for some months, are apt to conclude that they are already cured. No greater mistake could be made, for if they are allowed to drift back into the original pathological conditions their asthma will return. It is desirable to keep them under observation at regular intervals, which as time goes on can become less frequent.

I am, Sir, yours faithfully,

Newcastle-on-Tyne, March 26th. F. HARRINGTON.

THE ASTHMA RESEARCH COUNCIL.

To the Editor of THE LANCET.

SIR,—Allow me to endorse the letter of Dr. Millais Culpin published in your issue of March 24th, and to refer your readers to the correspondence on Psychogenic Asthma that appeared in THE LANCET about nine months ago, especially to my own letter,[1] in which I pointed out that such cases are but specific cases of the "conditioned reflex."

I am, Sir, yours faithfully,

Shortlands, Kent, March 26th. A. WOHLGEMUTH.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Culpin's letter, may I be allowed to point out that the Medical Advisory Committee to the Asthma Research Council realises fully the great importance of the psychological element in asthma, and for that reason Dr. R. D. Gillespie, physician for psychological medicine at Guy's Hospital, has already joined the committee.

I am, Sir, yours faithfully,

T. T. JEANS,
Hon. Secretary, Medical Advisory Committee.

Hove, March 26th, 1928.

*** We are asked to state that correspondence for the Asthma Research Council should be addressed to the Hon. Secretary of the Council, c/o The London Clinic, Ranelagh-road, London, S.W.1. Letters marked "Medical Advisory Committee" on the top left-hand corner of the envelope will be forwarded to Surg. Rear-Admiral Jeans.

[2] Ibid., February, 1928.

[1] THE LANCET, 1927, ii., 88.

TOXIC SYMPTOMS FROM PLASMOCHIN.

To the Editor of THE LANCET.

SIR,—I have been using plasmochin in the treatment of malaria for over a year with very satisfactory results. It may be of interest therefore to record that within the last week I have had four cases showing very definite toxic symptoms. All four were British, two were cases of subtertian malaria, and two were clinically malaria, no parasites having been found in the blood. In no case did the amount of plasmochin given exceed 0·06 g. in 24 hours, and in no case was the drug given for more than five consecutive days. The symptoms were cyanosis, very marked in two cases, and abdominal pain severe enough in two cases to prevent the patient sleeping during the entire night. These two patients were very much upset and complained bitterly that they felt that they had been poisoned. The supply from which the plasmochin employed was taken was part of a new consignment which had been in the country for less than six weeks.

I am, Sir, yours faithfully,

Khartoum, March 2nd, 1928. H. C. SQUIRES, M.D.

MEDICAL DIATHERMY IN MIDDLE-EAR DEAFNESS.

To the Editor of THE LANCET.

SIR,—I read with great interest the article on this subject by Dr. Dan McKenzie in your last issue. I have been using medical diathermy for these cases for the last 15 months and am in agreement with him on most points. I, too, have found that the cases most suitable for this method of treatment are those of Eustachian catarrh and chronic otitis media with sclerosis of the membrana tympani. My first case was a man, aged 69, who had suffered from deafness and severe tinnitus aurium for 14 years, the latter preventing sleep. His condition was the result of an old chronic otitis media. The tinnitus stopped during the first treatment and never returned, and the deafness has considerably improved. Whereas previously he had been deaf to the ticking of his clock, the mewing of his cat, and the barking of dogs, all these sounds became audible. He once said: "I like to go out and listen to the traffic."

My only criticism of Dr. McKenzie's article concerns the technique. I have tried various methods and am convinced that the following method is the best:—

I adopt the sitting posture and find that the patients prefer to sit than to lie on a couch, also the occurrence of vertigo afterwards is rare. The electrodes consist of two equal U-shaped plates 3 in. × 2½ in., cut from thin, flexible sheet metal. These are placed on the skull around the meatus and beneath the pinna. The anterior limb of each electrode bears a short "tab," which overlaps the external auditory meatus and makes contact with a plug of cotton-wool soaked in saline and inserted as far as the patient will allow. The metal electrodes are placed *directly* on the skin, good electrical connexion being obtained by means of a thin film of soap lather (shaving soap is the easiest to use). The electrodes are secured by two rubber sponges, one over each electrode, and a rubber bandage, which should be applied to pass over the vertex and the point of the chin.

I believe this method to be superior because: (1) It allows the patient to sit comfortably and with the minimum of restriction in an armchair and, if he wish, to read whilst having his treatment, which should last 15–30 minutes. (2) The electrodes, &c., are simple, and are easily and quickly applied in four minutes and removed in one. (3) The soap lather ensures perfect connexion by eliminating any danger from a greasy skin and uneven current penetration; and also the gravitation and drying-up so common with saline pads. (4) The path of the diathermy current is nearly 3 in. square and traverses the whole of the middle and inner ears and also the Eustachian tubes. A picture of the electrode is to be found in Sampson's "Practice of Physiotherapy."

One other point I must mention; one or two of my patients, particularly the younger cases of "otosclerosis," have improved in their general health and mental outlook. From being dull and listless and somewhat melancholic, they have become cheerful and of a more youthful appearance. If this is not a coincidence it can only be ascribed to the diathermy, as no other treatment of any kind was given.—I am, Sir, yours faithfully,

CEDRIC HILLIARD, M.B., B.Chir. Camb.

William-street, Knightsbridge, S.W., March 26th, 1928.

HYGIENE AT THE ROYAL HOSPITAL SCHOOL, GREENWICH.

To the Editor of THE LANCET.

SIR,—In view of Dr. J. A. Glover's remarks in the discussion on Juvenile Rheumatism at the meeting of the Section of Epidemiology of the Royal Society of Medicine on Feb. 24th (reported in THE LANCET for March 3rd, p. 447), it would seem to be suggested that the Royal Hospital School, Greenwich, has been allowed to exceed the number of boys for which accommodation is adequate. If Dr. Dudley's report is read, it will be seen that, whatever his personal opinion may be, he expressly states that the amount of air space and floor space is adequate according to the most accepted hygienic requirements. It is considerably better than that supplied in many other like institutions. The attack-rate for rheumatic fever in the Royal Hospital School in the Glover report is quoted as being 6 per 1000, in the Dudley report it is noted as 2 per 1000 in 1921, which is the correct number. This lower rate has been maintained since that year. I should be grateful if you would insert this letter, as, though I recognise that no reflection was probably in any way intended, the paragraph containing the remarks to which I am alluding might be construed to mean that those responsible for the health and care of the boys were lacking in the necessary vigilance, and were behind the times.

I am, Sir, yours faithfully,

PERCIVAL M. MAY,
Medical Officer to the Royal Hospital School,

March 23rd, 1928. Greenwich.

STEREO-FLUOROSCOPY.

To the Editor of THE LANCET.

SIR,—The two letters which appear in your issue of last week appear to charge me with a lack of fairness to British Radiology (Mr. W. E. Schall), and to British manufacturers (X-rays, Ltd.). As evidence of unfairness it is stated that apparatus of this kind was made years ago by British firms. But, did not I state in my communication of March 3rd that there was an apparatus similar in principle, designed for use with coils, in London, and I pointed out the difficulty of using that apparatus? I certainly did not state, as does Mr. Schall, that the apparatus was a complete success, or that the problem of stereo-fluoroscopy was satisfactorily solved. I rather agree with X-rays Ltd., that the methods in question did not prove to be of sufficient practical advantage to survive.

I can assure the gentlemen by whom these letters are signed that I yield to no one in my appreciation of the English manufactures, nor in my patriotism for the land of my birth, and if I travel to other countries to see the latest developments in medical or scientific apparatus, and if I publish what I see and hear, it is not with a spirit of unfairness to British manufacturers or lack of patriotism for England, but rather, that patients may have the advantage of the latest and best scientific developments and perhaps, even as the mouse in the fable, to be of some small help to the leonine manufacturers, in stimulating them to further and better efforts.

I am, Sir, yours faithfully,

F. HOWARD HUMPHRIS.

Great Stanhope-street, Park-lane, W.,
March 26th, 1928.

LIVER TREATMENT IN PERNICIOUS ANÆMIA.

To the Editor of THE LANCET.

SIR,—The following extract from a letter recently received from Australia may be of interest.

Dr. S. had treated a lady with signs of pernicious anæmia with poor results. After an absence of some time she put in an appearance at his rooms looking the picture of health. On inquiry as to what had produced this excellent result she said, "I went to a Chinese herbalist, who gave me a powder to take and this is the cause of my cure." The powder on examination looked like desiccated flesh and the patient said it was powdered liver of the carnivorous crow, an old Chinese remedy it appears. On further inquiry Dr. S. found that boys are regularly employed by Chinamen to catch crows for them, so that they may get the liver. Is it that the Celestials have been using for years a remedy which our men have only recently discovered?

Can any of your readers supply the answer? My correspondent is my father, who has recently given up active work in the profession, and Dr. S. is a well-known consultant in Melbourne.

I am, Sir, yours faithfully,
JOHN H. ANDERSON.

Ruthin Castle, North Wales, March 27th, 1928.

LOCAL FAT ATROPHY FOLLOWING INSULIN INJECTIONS.

To the Editor of THE LANCET.

SIR,—It may interest Drs. Carmichael and Graham to hear that I have a patient who developed a local fat atrophy following very large injections of insulin into the left thigh. It is now two and a half years since any insulin has been required and the thigh has returned to normal.

I am, Sir, yours faithfully,
Bridlington, March 26th, 1928. P. D. H. CHAPMAN.

The Services.

ROYAL NAVAL MEDICAL SERVICE.

Surg. Lt.-Comdr. G. E. Heath to be Surg. Comdr.
Surg. Lt. (D.) F. W. Watt to be Surg. Lt.-Comdr. (D.).

ROYAL NAVAL VOLUNTEER RESERVE.

Surg. Lt. S. W. Davidson to be Surg. Lt.-Comdr.

ROYAL ARMY MEDICAL CORPS.

Capt. E. S. Cuthbert to be Maj.
R. A. Kennedy to be Temp. Lt.
Temp. Lt. R. J. Monahan relinquishes his commn.

TERRITORIAL ARMY.

Capt. H. A. B. Whitelocke to be Maj.
Lt. O. F. W. Robinson to be Capt.
Lt. F. T. Birkinshaw resigns his commn.

ROYAL AIR FORCE.

The undermentioned Flight Lts. are granted permanent commissions in this rank: J. McM. Wilder and L. I. Hyder.

Temp. Capt. J. M. Jamie (Dental Surgeon, General List) is granted a temporary commission as a Flight Lt., on attachment to the R.A.F.

Flight Lt. C. T. Hastings (Capt., Army Dental Corps.) relinquishes his temporary commission on return to Army duty.

INDIAN MEDICAL SERVICE.

Majors to be Lieut.-Colonels: W. E. Brierley, J. B. Lapsley, C. H. Fielding, W. L. Watson, J. W. Barnett, Madan Lal Puri, R. B. Lloyd, A. C. Munro, Ram Nath Chopra, A. G. Tresidder, G. G. Jolly, H. Stott, A. A. C. McNeill, G. F. Graham, Maneck Dhunjishaw Wadia, T. D. Murison, Sohrab Shapoorji Vazifdar, J. J. H. Nelson, E. S. Phipson, F. F. S. Smith, and T. C. Boyd.

The undermentioned officers retire: Lt.-Cols. T. H. Gloster and L. Reynolds.

ROYAL VISIT TO MILITARY HOSPITAL.

On March 24th the King and Queen paid an unofficial visit to Queen Alexandra's Military Hospital, Millbank. They were received by Col. E. Ryan, the commanding officer, and Miss Osborne, matron-in-chief. The medical and surgical staff and sisters were presented to the King and Queen, who afterwards made a tour of the buildings.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

OFFICES REGULATION BILL.

ON March 20th in the House of Commons Miss WILKINSON asked leave to introduce a Bill to regulate offices and the employment of young persons therein; and for other purposes connected therewith. She said that the measure was designed to extend to people who worked in offices some of the protection that was at present given to those who worked in factories. The conditions in many big cities, especially owing to the great congestion at the present time, were rapidly growing worse, and it was felt that something ought to be done to protect the health of the men and women who worked in those offices. In one of the best and newest offices lately built in the City of London large provision was made for underground office accommodation. In the older buildings in the city where girls worked under-ground conditions were very bad indeed. They had also in these basement offices the enemy of damp. The effect on health was particularly bad at the present time, because many of these girls worked very long hours and special overtime at quarter days. A girl had written to her giving a description of the office in which she worked. It was only a cubicle with no windows and no ventilation, and five men besides herself worked in that unhealthy place. The girl added that the electric light had had a bad effect upon her eyes and she had been obliged to see an oculist, who said that her eyes were badly strained. One-third of the diseases of those who worked in offices were due to phthisis, and 122 out of every 1000 died from diseases which were caused by working in cramped spaces with bad light, bad ventilation, and very long hours. The Bill recognised the difficulty under which many employers worked at the present time. High rents were making overcrowding worse. The Bill threw the burdern of keeping the offices in a proper condition on the owner, but made provision for adjustment afterwards by the council. The Bill would prevent overcrowding; it would stop any premises being used as underground offices which were not so used on the date when the Bill passed into law, and briefly it made provision for adequate lighting and heating and proper sanitary accommodation.

Leave to bring in the Bill was granted without a division and the Bill was brought in and read a first time.

INVALIDING FROM THE NAVY: TUBERCULOSIS.

On Thursday, March 22nd, on the Report of Navy Estimates for 1928, Rear-Admiral BEAMISH said he wished to return to a subject which he had mentioned twice, that was the question of tuberculosis and the invaliding of men. One could not return to that particular matter too often because it was very serious. He realised that the Admiralty had their hands tied to some extent and that the question of invaliding was a matter for decision by secret and confidential instructions received by the Admiralty from the Treasury. He was not sufficiently conversant with Parliamentary rights to know whether they had any method whereby they could get hold of those instructions and see them. They ought to know more about them than they did at the present time. The Admiralty were condemned to be controlled by these regulations which imposed upon the men of His Majesty's Fleet very severe hardship when they were invalided. The extent of tuberculosis in the Navy had been higher for at least the last five years than it had been in the Army, and the conditions of life in the Navy were very largely responsible for that. He impressed upon the House the real importance of this matter and urged that the question should be adequately looked into and some change made, not only in regard to the actual methods of invaliding men, but in regard to the composition of the boards that invalided them, and in regard to the attributability as to the diseases and injuries for which the men were invalided.

The Incidence of Tuberculosis.

Dr. VERNON DAVIES said that he was tempted once again to press the question of tuberculosis in the Navy on the attention of the House. It was a most serious subject and affected a class of men who were not able to speak adequately for themselves. They had had statistics showing the number of cases of tuberculosis in the Navy and the extremely small percentage which got a pension or were held to be attributable—namely, 3 or 4 or 5 per cent. They could hardly wonder that these poor men who went into the Service physically fit in the prime of their youth and manhood and subsequently came out practically condemned to death must hold that in some way or another the Service had something to do with it. The different incidence of tuberculosis in the Army and the Navy to the detriment of the latter was perhaps not astonishing in view of the

cramped accommodation of the men in the battleships. After the previous debate on this matter in the House recently he looked into the matter further, and he would like to draw attention to a letter which he saw in the newspapers only the previous day, written by a man from Portsmouth, saying that there were 1600 men in that district who had been turned out of the Navy and whose disease had been held to be non-attributable to the conditions of service. He had looked into some statistics, and comparing tuberculosis in the Navy and in civil life, particularly for 1925, he was astonished to find that there was a different incidence in the tuberculosis rate in civil life and in the Navy. In a certain period of civil life between 20 to 25 years of age he thought the incidence of tuberculosis was decreasing, but in the Navy it was increasing. At first sight that would lead one to suspect that there was some condition in the Navy which was causing a change essentially different from what happened in civil life. He was recently informed that a committee was sitting to consider this matter. When he inquired when the last meeting was held he was told that it was some months previously because one of the members had not been very well. If that sort of thing went on this committee would be sitting during the next Parliament, and perhaps the Parliament after that, and he was anxious that something should be done at once. On the lowest computation there were some hundreds of men in this country slowly but surely dying of consumption, men who had served in the Navy and who were convinced that they had contracted the disease there; yet nothing was being done for them, except what they might get from the National Health Insurance scheme—15*s.* a week. A man had to be kept on that. A baby four or five months old could take 10*s.* worth of milk every week. This disease required so much nourishment that it was absolutely impossible for any tuberculosis case to live on the money which came from the National Health Insurance scheme. This state of matters was a scandal to the House of Commons, a scandal to the Admiralty, and a scandal to the country.

Lieut-Colonel HEADLAM (Parliamentary Secretary to the Admiralty), replying to the debate, said that the question of invaliding from the Navy was exercising very earnest attention and a committee had been appointed to go into the whole of the details. The whole question of hygienic conditions in the Navy had been referred to a consultative committee of experts outside the Admiralty.

The Report of the Navy Estimates was agreed to.

CONSOLIDATED FUND (NO. 1) BILL: DISTRESS IN COAL-MINING AREAS.

IN the House of Commons on March 26th, on the Order for the second reading of the Consolidated Fund (No. 1) Bill,

Mr. RAMSAY MACDONALD raised the question of distress in the coal-mining areas. He said that the Labour Party had recently sent a committee to inquire into the position in South Wales. In one mining valley they found schoolchildren suffering from lack of nourishment and there was a most distressing lack of boots and stockings. Two salient points in the survey of the County of Monmouth were, first, the constant deterioration of the financial position of the people, and secondly, the deterioration of the human beings who had to go through the present terribly trying conditions. In Blaina, 423 out of 3045 children were subnormal from various causes and the health of the mothers was steadily growing worse. The House could not allow this to go on. Many of these people, also, were falling out of National Health Insurance, which would result in the loss not only of all benefits, but ultimately of the old-age pension at 65 and the widows' and ophans' allowances. The first duty was to save the infants. They must see that all maternity and infant welfare equipment was up to date. They must also face the question of the provision of boots and shoes and clothing, and of keeping the children at school. The community should take these obligations on its shoulders and not leave it to private charity.

The Help Given by Public Bodies.

Mr. NEVILLE CHAMBERLAIN (Minister of Health) said that whatever measures they might take ultimately to cope with the problem, the process must be slow. They had to contemplate some period during which the position must be most carefully and sympathetically watched. There were various agencies and public bodies in every district whose duty it was to look after persons who were so impoverished that they were no longer able to look after themselves. He had to ask himself whether these agencies in South Wales were breaking down and whether the conditions there were so dangerous to health, or so different from those in other large industrial areas, where there were unemployment and distress, as to justify the employment of fresh agencies to supplement those already in existence. The report of the two Labour Members who went to South Wales was singularly moderate in its comments on the state of the health of the people there. They could not have such distress, unemployment, and impoverishment without some effect on the health of the people, but, while they must keep a very careful eye on what was happening to the public health, and especially the health of the children and expectant mothers, there was no reason up to the present to believe that it had reached any very disquieting or serious point. Until he was satisfied that the efforts of the people of South Wales to help was really exhausted he was most unwilling to entertain the idea of using for the undoubtedly serious shortage of boots and clothing among the children public funds which had to be paid for by other districts which also had distress to deal with. The Government's policy was to transfer the population from hopelessly derelict areas to other places.

Mr. PETHICK-LAURENCE said that the boards of guardians were refusing to find money for certain things which the doctors, ministers of religion, and Chambers of Commerce were urging them to do in the distressed areas. Where children were ill-nourished, school meals were provided by the local authority. On Saturdays and Sundays, the teachers took the food to the children in their homes, but the local guardians, in every case where that was done, deducted 2*s.* a week out of the money which they might give in relief to the families of the children so fed. This neutralised the benefit which the feeding conferred on the children. He urged that the rules should be relaxed, and that the guardians should be instructed not to deduct this money. They ought also to be allowed to provide boots for the children who needed them.

The Bill was read a second time.

COÖRDINATION OF THE FIGHTING SERVICES.

On March 27th, on the Order for the third reading of the Consolidated Fund Bill,

Sir R. HUTCHISON suggested an alteration in the administration of the fighting services in order to secure greater coördination and control than existed at the present time. During the war, he said, control was exercised by the War Cabinet, but since the Armistice that body had disappeared and nothing had taken its place. The fighting services had dropped back into their pre-war position, each being under a departmental chief. If they could secure unified control it would be possible to get a far better application of the forces wherever they were required in the world. There would be considerable advantage in such a system in regard to hospitals and other matters. It was also possible that they might get a wider and bigger medical service by bringing the medical services of the Army, Navy, and Air Force under one control.

Hospital Coöperation.

Mr. BALDWIN (Prime Minister) said that he would like to show, by way of illustration, what was being done by coöperation between the hospitals at the present time. In that respect there had been a move forward in the last year or two. The Royal Air Force maintained no separate hospital at home, except the two big isolation stations at Halton and Cranwell. They had no hospital in the neighbourhood, but there was a small officers' hospital of 25 beds at Uxbridge for dealing with flying accidents which might occur at that centre. But abroad, where the Royal Air Force were in control, they maintained their own hospitals, and during 1926 there were up to 3000 admissions of personnel of the Navy, the British and Indian Armies, and local forces of Iraq and Palestine treated in the Royal Air Force hospitals. The military hospitals at Cosham and Devonport were closed in that year, and arrangements were made for the sick of the Portsmouth military area and of the military stations in the Devonport area to be treated in the Royal Victoria Hospital, at Netley, or the Royal Naval Hospital, at Haslar, and the Royal Naval Hospital, at Plymouth. No less than 3000 of the Royal Air Force personnel received treatment in the Naval, Army, and Civilian hospitals during the last 18 months. In the same way, there had been considerable treatment of Air Force and Army patients in the Naval hospitals, both at home and abroad. The possible pooling of other hospital arrangements had been examined and, in some cases, had been found impracticable, but there were some places which were still under investigation. The Air Force made no general contracts in regard to medical supplies itself. They took the existing Army contracts, and standardisation and pooling had been agreed to in principle in regard to the ambulance trains, and the details were being worked out. The India Office were being invited to coöperate and a number of other matters were being studied now by the general medical services, &c. In research coördination was effected through three coördinating boards for chemistry, physics, and engineering.

The Bill was read a third time.

PETITION AGAINST MOTOR TAX.

Colonel HOWARD-BURY presented to the House of Commons on March 27th a petition from the Automobile Association signed by 920,000 motor owners and users. The petitioners stated that they were gravely concerned at the continuance of the system of motor taxation imposed by the

Finance Act, 1920, which was inequitable and unjust to the vast majority of motor users. They humbly prayed that the present method of motor taxation should be amended in favour of a flat rate duty on petrol plus a small registration fee.

HOUSE OF LORDS.

TUESDAY, MARCH 27TH.

PUBLIC HEALTH (DESTRUCTION OF VERMIN) BILL.

Lord STRATHSPEY, in moving the second reading of the Public Health (Destruction of Vermin) Bill, explained that the measure provided that if it appeared to the local authority on the certificate of a medical officer, or sanitary inspector, that any articles in any premises used for human habitation were infested with vermin, or were likely to be so infested, the local authority, at their expense, should cause those articles to be cleansed, disinfected, or destroyed. If it appeared to the local authority, on the certificate of the medical officer or the sanitary inspector, that any premises used for human habitation were infested with vermin, the local authority should give written notice to the occupier, or the owner if the premises were vacant, requiring him to cleanse the premises. The notice might require the removal of wallpaper and other covering on the walls. As a penalty for default, a fine not exceeding £5 was provided, and a daily penalty of 10*s*., and the local authority might do the work and recover the cost. Clause 3 provided that on the application of any person, the local authority might take such measures as they deemed necessary to free that person and his clothing from vermin. Where it appeared to the local authority, on a report from the medical officer, that any person or his clothing was infested with vermin and that person consented to be removed to a cleansing station, the local authority might cause him to be so removed. If he did not consent, a petty sessional court, if satisfied on the application of the local authority that it was necessary, could make an order for his removal to the cleansing station. It was provided that the cleansing of females should be effected only by a registered medical practitioner, or by a woman duly authorised by the medical officer. As soon as the occupier of a house became aware that it was infested he was required to send notice to the medical officer of health, and if a person became infested he must notify the medical officer.

Rejection Moved.

Lord BANBURY moved the rejection of the Bill, which, he said, was absolutely unnecessary. It enacted clauses already in existence, and some of the new clauses converted the private individual into a police officer. They compelled him to interfere in other people's business, and to do the business of the local authorities, who already had powers through their medical officers and sanitary inspectors to find out if people had got vermin on them or not.

Viscount GAGE said that the Minister of Health was not convinced that any real defect in regard to these matters existed under the present law.

After further discussion the Bill was rejected without a division.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 21ST.

Training and Supply of Midwives.

Sir ROBERT THOMAS asked the Minister of Health whether he was prepared to institute an inquiry into the supply, pay, and training of midwives, with special reference to their distribution in rural areas.—Sir KINGSLEY WOOD (Parliamentary Secretary to the Ministry of Health) replied: My right hon. friend is taking steps to set up a committee to enquire into the general question of the training and supply of midwives.

THURSDAY, MARCH 22ND.

Diphtheria in London Elementary Schools.

Mr. OTHO NICHOLSON asked the Minister of Health if he was aware that parents of children attending elementary schools in the County of London were not notified of cases of diphtheria occurring in such schools and given an opportunity of isolating the child who had been attending; and that there was no disinfection of class-rooms in which cases had occurred; and what action he proposed to take.—Lord EUSTACE PERCY replied: The arrangements made by the London County Council for dealing with cases of diphtheria occurring in elementary schools are based on experience extending over 20 years, and I am advised that all reasonable precautions are taken. I do not, therefore, think that any intervention on my part is called for.

Death of a Child after Operation.

Mr. MACQUISTEN asked the President of the Board of Education whether he would inquire into the circumstances of the death of the son of Mrs. Maggie Potts, of Oulton, Wigton, Cumberland, who was a healthy child in Oulton school until, without the consent and in spite of the protests of his mother, he was operated on for tonsils and adenoids, with the result that he died, and under what authority such action was taken.—Lord EUSTACE PERCY replied: I have already received a report on this case from the school medical officer and I am sending my hon. friend a copy. I understand that the concurrence of the boy's mother was obtained before the operation was performed. The boy was operated upon at a hospital by a specialist; he was kept in the hospital for two nights after the operation, and was apparently quite well when discharged. I am advised that death was due to complications which subsequently arose, and that this regrettable occurrence was not due to any defect or failure in the authority's arrangements for treatment.

MONDAY, MARCH 26TH.

Medical Staff in the Crown Colonies.

Mr. WALTER BAKER asked the Secretary of State for the Colonies the authorised strength of the official medical staff in each of the Crown Colonies; whether any colony had a staff which was not up to strength; and what steps were being taken to deal with any shortage.—Mr. AMERY replied: As regards those Colonial medical appointments which are usually filled by recruitment in this country, it is only in the West African Medical Staff that the number of vacancies is considerable. For most other Colonial medical services there is a surplus of candidates. When vacancies occur they are advertised in the medical and other press and in filling appointments the Colonial Office receives assistance from the Universities, the Medical Schools, and the British Medical Association. Latterly a number of applications have been received from Dominions candidates. The following figures give the authorised strength (A.S.) and vacancies (V.) on the official medical staff in the various Crown Colonies:—

Colony.	A.S.	V.
S.A. High Commission—		
Basutoland	11	0
Bechuanaland	6	0
Swaziland	2	0
Kenya	94	6
N. Rhodesia	16	1
Nyasaland	22	0
Somaliland	11	0
Tanganyika	114	4
Uganda	77	2
Zanzibar	19	0
Gambia	6	0
Gold Coast	100	20
Nigeria	161	27
Sierra Leone	26	0
Cyprus	38	1
Gibraltar	7	0
Palestine	55	1
Ceylon	363	0
Mauritius	18	1
Seychelles	5	0
Fiji	68	0
W. Pacific High Commission—		
Gilbert and Ellice Islands	5	0
Brit. Solomon Isl.	3	0
St. Helena	2	0
Hong-Kong	18	4
Wei-hai-Wei	2	0
Straits Settlements and Malay States	310	10
Bahamas	9	0
Barbados	11	1
Jamaica	57	0
Cayman Island	1	0
Turks and Caicos Isl.	2	0
Leeward Islands	22	2
Trinidad	39	0
Windward Islands	19	1
Bermuda	4	0
British Guiana	43	0
British Honduras	8	0
Falkland Islands	3	0

Note.—The figures of authorised strength relate to the whole establishment of medical officers, both those who are recruited from this country and those who are recruited locally. The figures of vacancies relate only to appointments usually filled from this country, as it is only in regard to these that definite information is available.

Slum Clearances.

Sir WILFRID SUGDEN asked the Minister of Health what steps he was taking to assist slum clearance by alterations to Section 46 of the Housing Act, 1925; if the improvement scheme in Leeds, held up for two years by this section, was under his consideration as to its results; and what steps he proposed to take as to other schemes in the country disadvantageously affected also by the same section.—Mr. CHAMBERLAIN replied: The whole subject of slum improvement is receiving my personal consideration, but I am not yet in a position to state when it will be possible to bring in legislation; the report made following the inquiry into the particular scheme to which my hon. friend refers has been considered and my decision will be communicated at an early date.

TUESDAY, MARCH 27TH.

Notification of Infectious Diseases.

Mr. SHEPHERD asked the Minister of Health whether he would consider the question of so amending the Infectious Disease (Notification) Acts that any suspected infectious disease would have to be reported without awaiting the results of a bacteriological examination, where such disease was infectious in its early stages.—Mr. CHAMBERLAIN replied: No, Sir. The Acts in question do not require notification to be delayed pending the results of a bacteriological examination, and notifications are frequently made solely as the result of clinical examination.

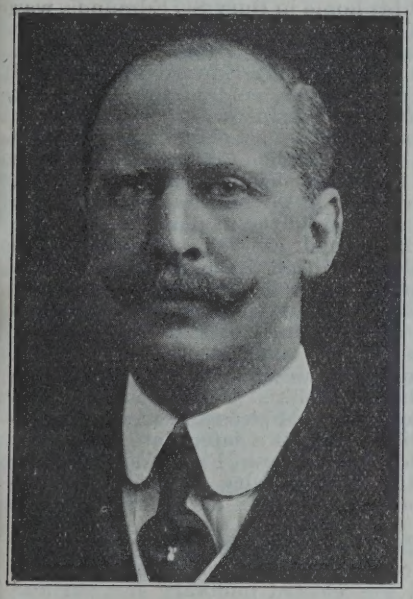
Obituary.

HUGH JAMES MOORE PLAYFAIR, M.D. LOND., F.R.C.P. LOND., F.R.C.S. ENG.,

CONSULTING OBSTETRIC SURGEON TO KING'S COLLEGE HOSPITAL.

THE death was announced last week of Dr. Hugh James Moore Playfair, the well-known obstetrician, which occurred at his house in London on March 25th, in the sixty-fourth year of his age. For the past few years his health had not been good, a fact which led to his retirement from the post of obstetric surgeon to King's College Hospital just three years ago.

Hugh Playfair was the son of General Archibald Playfair and the cousin of the well-known gynæcologist, William S. Playfair. He was born in Edinburgh, and received his early education at Fettes College, whence he proceeded for medical training to the schoolof King's College Hospital. He qualifiedas L.R.C.P. Lond.,M.R.C.S. Eng. in 1890, and graduated M.B. Lond. in the same year, proceeding to the M.D.degree in 1892. He held the usual resident appointments at the hospital, after which he took out a post-graduate course in Berlin, and returning to London was appointed curator of the anatomical and medical museum at his hospital and assistant demonstrator of anatomy. He had already been house accoucheur, and now decided to adopt the career of obstetric physician. He took the M.R.C.P. Lond., and three years later the F.R.C.S. Eng., and was also appointed physician to the Royal Waterloo Hospital for Women and Children. He filled the post of obstetric tutor in the medical school of King's College Hospital, and in 1904 became assistant obstetric physician and lecturer on practical obstetrics. From this time onward for 30 years Playfair's life was fully absorbed in professional work along his selected lines. He became obstetric and gynæcological surgeon to King's College Hospital; he examined in his subjects for the Conjoint Board of the Royal Colleges, and he wrote upon it in hospital and society reports, and occasionally in the medical journals; while in the medical school he was remarkable for the assiduity with which he taught his pupils as well as for the practical interest which he took in their lives. He held, in addition, gynæcological posts at the Metropolitan Hospital and at no less than three cottage hospitals, so that his practical experience became very large and varied.



DR. HUGH PLAYFAIR.

Photograph by Lafayette.

Mr. W. Gilliatt writes: "Hugh Playfair's death at the comparatively early age of 63, leaves a gap amongst King's men that cannot be filled. There was no one whose opinion was more eagerly sought, whether upon a difficult case, at a medical board, or by a student planning his career. Playfair brought to bear on each problem the same lively interest and reasoned judgment. He possessed the quality, rare in our day, of courtliness unspoiled by affectation, which made him hosts of friends in every walk of life. Many generations of students and nurses will grieve the loss of a most able and patient teacher. His lectures and ward rounds were always crowded, and the subjects so simplified by him as to become clear even to the newest clerk. When teaching he gave freely of time and effort. Though energetic by nature and brisk in manner, he never appeared in a hurry, and no contretemps ever ruffled him. In the midst of a busy life, which daily became more exacting, he kept a close interest in the athletic side of the medical school. He frequently attended the hospital Rugby football matches, and was a keen supporter of the medical and musical societies. Even after his retirement from the hospital three years ago, owing to failing health, he never lost touch with its affairs, maintaining the same keen interest in the hospital and medical school. There is little doubt that Playfair excelled in the clinical side of his special subject, and to those who had the privilege of working with him, it very soon became obvious that his opinion in the difficulties of gynæcology and obstetrics was second to none. He was unusually expert in obstetrics, and to see him carrying out practical obstetric manipulations was a wonderful lesson. During the many changes which followed each other in his branch of medicine, Playfair always kept himself abreast of thought and practice, as gynæcology developed from a branch of medicine to a surgical subject.

"As a colleague he was ideal, encouraging, always interesting and unusually generous to his juniors, who will sorely miss his balanced opinion and wise counsel. The feeling of all of us at King's is that we have lost a valued friend, a part of the institution itself, rather than a member of the staff. His charm of manner, cheerful friendliness, and deep sympathy were felt by all who worked with him. It can truthfully be said of Hugh Playfair that he never said a spiteful thing nor did a mean one."

In private life Dr. Hugh Playfair was known as a learned connoisseur of the arts. He married in Paris in 1905 Miss Eva Journault, by whom he had no children, but he adopted the son of his late younger brother, Arthur Playfair, the well-known actor; the boy is now a naval cadet. Dr. Playfair was an Associate of King's College and a Chevalier de la Légion d'Honneur. His death is regretted by a large number of personal friends and of patients, who owed much to his professional skill and advice.

LIONEL RICHARD FIFIELD, F.R.C.S. ENG.

ON March 21st, as we recorded last week, Mr. L. R. Fifield died from injuries sustained on the previous evening, when he and his wife were knocked down by a motor-car. The career thus ended was of exceptional promise, and his death at the age of 30 is felt with deep regret by friends at the London Hospital and elsewhere.

Fifield's medical work hardly began until the end of the war, and it was as a combatant that he enlisted in the Army. After serving with distinction in France, where he was wounded and received a commission, he entered the London Hospital in January, 1919. He had then only passed the preliminary scientific examination of the Conjoint Board, but succeeded in obtaining the M.R.C.S. Eng. in October, 1921, after two and a half years' work instead of the the usual four years. In December, 1923, less than four years after beginning work for the second professional examination, he became a Fellow of the Royal College of Surgeons of England at the early age of 25. He was soon recognised as a man of unusual ability, and after qualification held various resident appointments, including that of house surgeon to the Surgical Unit. For some years he was demonstrator of anatomy, and in 1925 was appointed surgical first

assistant to Mr. Hugh Lett and Mr. W. S. Perrin, a post which he held at the time of his death.

Clear reasoning and lucid explanation made him an excellent teacher, and he had already published two useful books, one on infections of the hand, and the other on minor surgery. The same qualities of clearness and brevity are seen in them, as in his contributions to our columns on diverticulitis and other subjects. For an essay on New Growths of the Bladder he was recently awarded the Buckston Browne Prize of the Harveian Society. This embodies an account of experiments on animals in connexion with the transplantation of the ureters into the intestine, and is being published in book form; it was in the press at the time of his death. A rapid worker, Fifield was endowed with a remarkable memory and was a quick, yet careful, operator. His judgment was good and his fine physique gave him an energy which was seemingly inexhaustible. In the Law Courts he was acquiring a reputation as a man of integrity, a reliable witness, and a surgeon of sound knowledge and argument. This exceptional equipment for his profession was associated with a friendly and unassuming nature. His juniors found him easy to get on with and learnt the more from him because he was easily approachable; whilst his keen ambition as a surgeon was never allowed to affect his generous and genial outlook on life.

The funeral, on March 23rd, was attended by a large number of the staff, residents, and students of the London Hospital.

RICHARD JOHN KINKEAD, M.D. DUB.

THE death of Dr. R. J. Kinkead, professor of obstetrics and gynæcology at University College, Galway, occurred at an advanced age on March 18th. He had been in failing health for some years, though he continued to work until a few months ago. Educated in the school of the Royal College of Surgeons, Dublin, and at Trinity College, Dublin, Dr. Kinkead obtained his qualifications at an early age, and at once began practice in Tuam. Some ten years later, in 1876, he was appointed professor of obstetrics in Queen's College, Galway, then a constituent college of the Queen's University of Ireland. He retained that post until the time of his death, through the many changes the College has undergone; but for the last few years many of his duties were performed by a deputy. He was also gynæcologist in the County Galway Hospital, and for many years medical officer of H.M. Prisons at Galway.

Dr. Kinkead's ability and character speedily gained for him a commanding position in the medical profession of the West of Ireland, and he had a large consulting and general practice. He took an important share in professional organisation, and was President of the Irish Medical Association for a term. For many years he was a member of the Council of that body, and was vice-president for Connaught. On his retirement from active work he was elected an honorary member of the Association in recognition of his manifold services to the profession. A man of solid intellect, he always found time for reading, and he often surprised his friends by a knowledge of unexpected by-paths in literature and art. What was most impressive about him, however, was his independence and his strength of character. He accepted his ideas from no one. He made up his mind deliberately and thoughtfully, and always with consideration for the views of others, but once his mind was made up it was difficult to move him. He had a high idea of the dignity of the medical profession, and no one in the Ireland of his day did more by example to make others respect the profession. As medical officer of the prison he allowed no interference from anyone—however high in the official world—with what he conceived to be the powers and prerogatives of the medical officer. He held that it was the medical officer's duty to stand between the rigour of prison routine and a sickly or delicate prisoner, and many of the political prisoners who were under his care at one time or another expressed their deep respect for his humanity and independence. By the people of the West of Ireland and by his professional colleagues he was equally respected. In his younger days he frequently contributed to the medical journals, and he wrote a useful book, "The Irish Medical Practitioner's Guide."

Dr. Kinkead was twice married, his second wife dying a few years ago. He had two sons, both of whom lost their lives as young men; one of them, an officer in the Royal Army Medical Corps, being killed during the war. Four daughters survive him.

HENRY GOFF KILNER, M.B., B.S.LOND.,

HON. SURGEON TO THE WEST SUFFOLK GENERAL HOSPITAL.

Dr. Henry Goff Kilner, who died at the age of 42, on March 17th, at his home in Bury St. Edmunds, was the second son of Dr. Charles Scott Kilner, and the fourth in succession of that family to practise medicine in the city. Educated at King Edward VI.'s School in Bury, Henry Goff Kilner entered the Middlesex Hospital where, after a successful career as a student, he gained the senior Broderip scholarship. Having qualified in 1909 at the English Colleges, he held the appointments of house physician, house surgeon, and obstetric house physician at the hospital, and later was demonstrator of anatomy in the medical school. He graduated M.B., B.S. Lond. in 1912, and held an appointment at St. Peter's Hospital, Covent Garden. On the outbreak of war, he was gazetted Second Lieutenant to the 5th Suffolks. He served as a combatant till the Army Order of the summer of 1915 requisitioned medically qualified men to associate themselves with the R.A.M.C., and was present at Gallipoli, where he served in a hospital ship. Subsequently he was on the headquarter staff at Mudros and then in Egypt with the 29th Division. At a later date he served with the 7th Field Ambulance in France and became D.A.D.M.S. to the 2nd Cavalry Division. While there he was awarded the Croix de Guerre and was twice mentioned in despatches. Returning to Bury St. Edmunds after the war, Kilner acted as surgeon to the hospital for disabled men under the Ministry of Pensions, and was elected honorary surgeon and honorary radiologist to the West Suffolk General Hospital, an appointment which he was holding at the time of his sudden death.

An intimate friend writes: Kilner could never spare himself where he felt that anyone was in need of him. His kindness was unbounded and it is many a lame dog he has helped over a stile. The hundreds who thronged the churchyard at the funeral bore eloquent testimony to the regard and respect of those whom he had benefited. He was the loyalest of friends and a cheerful and charming companion. The wind, the sun, and the open country were as the breath of life to him. He was a keen naturalist and archæologist, and never happier than when tramping over his native soil in search of some rare bird or showing a friend one of the many architectural glories with which his countryside abounds. He loved life and his spirit of enjoyment was infectious.

Dr. Henry Kilner married in 1916 Olive, daughter of the late Mr. R. T. Simpson, of Horsecroft, Bury St. Edmunds, who survives him with two young children.

ALFRED THOMAS TUCKER WISE, M.R.C.S.ENG., M.D. BRUX.

Dr. Tucker Wise, who died at a nursing home in London after a few days' illness on March 23rd, was in his eightieth year, having been born at Plymouth on Feb. 4th, 1849, son of Thomas Tucker Wise, Fleet Paymaster, R.N. He was educated at Eastman's Royal Naval Academy with a view to following his father, and had actually reached the grade of assistant paymaster before deciding for a medical career. He took his clinical studies at St. Mary's Hospital, London, qualifying in 1876, and filling a

series of house appointments at the hospital, where he was also vice-president of the Medical Society. At the same time he passed the M.D. Brux. with honours in obstetric medicine, and proposed to settle in London, towards which end he obtained appointments at the Western General and Kilburn Dispensaries, and the Infirmary for Consumption in Margaret-street. Consideration for his own health, however, led to a period of residence at various places in the High Alps, among them the Kursaal at Maloja, where he acted as resident physician. A contribution in 1881 on the Effects of Altitude on Phthisis was one of the first serious studies of the Alpine climate, and was followed by a brochure entitled "Alpine Winter in its Medical Aspects," which ran through five editions. Having obtained the Swiss Federal diploma by examination at Geneva University in 1891 Dr. Wise became one of the small group of British medical men at liberty to practise his profession in any part of Switzerland, and thereafter he regularly wintered at Montreux, where he had a large seasonal practice. Here he devised a postural method of treating pulmonary tuberculosis which encouraged drainage of the lung and induced artificial hyperæmia of the apex, and no doubt the views which he then expressed, in common with Dr. W. Ewart and others, ameliorated the lot of patients unable to empty the contents of bronchiectatic cavities other than by troublesome bouts of coughing. His interest in the physiology of climate was not limited to the Alps, and he addressed American medical congresses on more than one occasion on the climate of the Balearic Islands and other southern stations in Europe. During the war Dr. Wise acted as medical superintendent to the Devon County Sanatorium; recently he had been living in retirement at Strete, near Dartmouth. His favourite recreations were physical labour in the country, especially woodwork and forestry, and he was reputed something of an expert at billiards. His wife was a daughter of Mr. W. Hayne Maunder, of Malahide.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At recent examinations the following candidates were successful in the undermentioned subjects:—

Surgery.—P. C. Basu, Calcutta; M. Hurwitz, Leeds.
Medicine.—E. E. Bowen, Middlesex Hosp.; K. J. M. Graham, Charing Cross Hosp.; H. J. Harcourt, St. Thomas's Hosp.; M. Hurwitz, Leeds; N. S. J. Roberts (Section II.), Bristol and Royal Free Hosp.
Forensic Medicine.—K. D. C. Beckitt, Charing Cross Hosp.; E. E. Bowen, Middlesex Hosp.; M. Hurwitz, Leeds; H. S. Marks, Guy's Hosp.; E. O. Watson, St. Bart.'s Hosp.; C. C. F. White, Guy's Hosp.; W. Ziv, Bâle and London Hosp.
Midwifery.—H. W. Maurer, St. Mungo's, Glasgow; C. K. McCoan, St. Mary's Hosp.; L. W. Sanders, Manchester and Charing Cross Hosp.; W. Ziv, Bâle and London Hosp.

The Diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery: E. E. Bowen, H. J. Harcourt, and N. S. J. Roberts.

VICTORIA UNIVERSITY OF MANCHESTER.—At recent examinations the following candidates have satisfied the examiners:—

DIPLOMA IN PUBLIC HEALTH.

W. C. V. Brothwood, Miriam Florentin, Thomas Peirson, J. B. Wiley.

DIPLOMA IN PSYCHOLOGICAL MEDICINE.

Part I.—Richard Handley, J. E. Howie, W. H. Shepley, Harry Stafford.

The Dauntesey senior medical scholarship has been awarded to R. V. Wright, and the Dauntesey junior medical scholarships to C. H. Gray and Philip Zimmerman.

UNIVERSITY OF LIVERPOOL.—At recent examinations the following candidates were approved:—

DIPLOMA IN MEDICAL RADIOLOGY AND ELECTROLOGY.

N. J. Barton, R. V. Berrington, E. O. Fox, Norah M. Walker.

DIPLOMA IN TROPICAL HYGIENE.

R. R. Evans, W. J. Laird, H. V. R. Miller, G. H. Pearson, J. H. Pottinger, S. A. Wilkinson.

FINAL EXAMINATION FOR M.B. AND CH.B. DEGREES.

Part I.—J. D. Bright-Richards, J. P. Flanagan.
Part II.—A. L. Beresford, A. E. Carrol, A. Gardner, W. W. Gerrard, G. A. Talwrn-Jones.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—An election to fill four vacancies on the Council of the College will take place on July 5th, and the list of candidates is now closed. The vacancies occur through the death of Mr. Thelwall Thomas, and the retirement in rotation of Sir Anthony Bowlby, Sir D'Arcy Power, and Mr. F. J. Steward, a vice-president of the College. Mr. Steward offers himself for re-election, and the other candidates, in order of seniority as Fellows, are: Mr. L. P. Gamgee, Mr. R. G. Hogarth, Mr. T. P. Legg, Mr. H. W. Carson, Mr. J. P. Lockhart-Mummery, Mr. Russell Howard, Sir Crisp English, Mr. Harold Wilson, Mr. C. C. Choyce, Mr. R. E. Kelly, and Mr. Robert Milne.

UNIVERSITY OF EDINBURGH.—The Senate has decided to confer the degree of doctor of laws on Sir John Rose Bradford, P.R.C.P. Lond.; Dr. George Lovell Gulland, formerly professor of medicine, Dr. James Haig Ferguson, formerly senior lecturer in midwifery, and Dr. Robert A. Fleming, formerly senior lecturer in clinical medicine in the University; Mr. H. S. Wellcome, founder of the Wellcome Research Laboratories and the Wellcome Bureau; and Dame Mary Scharlieb, M.D.

SWINEY PRIZE FOR MEDICAL JURISPRUDENCE.—The next award of the Swiney prize, which consists of a cup, valued at £100, and money to the same amount, will be made in January, 1929. The award is made jointly by the Royal Society of Arts and the Royal College of Physicians on every fifth anniversary of the death of Dr. Swiney, and is given for the best published work, alternately, in Medical and General Jurisprudence. The award in 1929 is offered for a work in Medical Jurisprudence. Particulars may be had from the Secretary of the Royal Society of Arts, John-street, Adelphi, London, W.C. 2.

UNIVERSITY OF LONDON.—At a meeting of the Senate held on March 21st Mr. W. W. Jameson, M.D., M.R.C.P., was appointed as from Jan. 1st, 1929, to the University Chair of Public Health, tenable at the London School of Hygiene and Tropical Medicine. Dr. Jameson received his medical education at Aberdeen University, the Rotunda Hospital, Dublin, and University College, London. He graduated in Arts at the University of Aberdeen in 1905, and in Medicine, with distinction, four years later. In 1912 he proceeded to the M.D. Degree with commendation, and in the following year he became M.R.C.P. Lond. From 1914–19, having taken the D.P.H., Dr. Jameson held the offices of Assistant and Lecturer in the Department of Hygiene at University College, London, and Assistant and Deputy Medical Officer of Health for the Metropolitan Borough of Stoke Newington. From 1915–19 he was on war service and was mentioned in dispatches. In 1919 he returned to University College, and in 1920 was appointed Medical Officer of Health and School Medical Officer for Finchley, and later Deputy Medical Officer of Health for the Metropolitan Borough of St. Marylebone. Whilst holding these appointments he studied law and was called to the Bar in 1922. In 1925 he was invited by the Town Council of the Borough of Hornsey to become their Medical Officer of Health and School Medical Officer, which posts he still holds, and a year ago he took over the office of Medical Superintendent of the Hornsey, Finchley and Wood Green Joint Isolation Hospital. Since 1926 he has also been Lecturer on Public Health and Preventive Medicine at Guy's Hospital Medical School.

The degree of D.Sc. in Anatomy was conferred on Mr. W. E. Le Gros Clark, university professor of anatomy at St. Bartholomew's Hospital Medical College, and the degree of D.Sc. in Biochemistry on Mr. F. W. Fox for a thesis on sterol metabolism.—Dr. John Fawcett has been elected chairman of the committee of medical members of the Senate, and Sir John Rose Bradford, F.R.S., vice-chairman of the University College Committee.

Mr. Walter Spencer proposed, and Dr. Graham Little, M.P., seconded, a resolution "That the attention of the Senate be drawn to the limitations placed upon the medical education of women undergraduates and that a committee be appointed to consider the question and report to the Senate thereon." This motion was carried and the committee was constituted as follows: Sir William Beveridge (vice-chancellor), Prof. S. L. Loney (chairman of Convocation), Prof. L. N. G. Filon, F.R.S. (chairman of the Academic Council), Dr. Graham Little (chairman of the External Council), Sir Holburt Waring (chairman of the Finance Committee), Mr. Walter Spencer, the Rev. W. R. Matthews (Dean of King's College), Prof. W. P. Halliday (principal of King's College), Sir Andrew Taylor (chairman of the Managing Committee, University College); Miss Ethel Strudwick (principal of St. Paul's School for Girls), and Miss Margaret Tuke (principal of Bedford College for Women).

AFTER April 2nd the East End Mothers' Lying-In Home will be known as the East End Maternity Hospital.

UNIVERSITY OF OXFORD.—Dr. C. G. Douglas has been reappointed demonstrator in general metabolism, and Dr. C. W. Carter has been appointed demonstrator in biochemistry.

UNIVERSITY OF DUBLIN.—The honorary degree of Master of Surgery is to be conferred on Sir John Bland-Sutton.

Sir Humphry Rolleston, Regius Professor of Physic in the University of Cambridge, has been made an honorary doctor of laws of Jefferson Medical College, Philadelphia.

ROYAL SOCIETY OF MEDICINE.—The Society's house and library will be closed from Thursday, April 5th, to Tuesday, April 10th, both days inclusive.

MEDICAL GOLFING SOCIETY.—The semi-finalists in the society's spring knock-out tournament are: E. Laming Evans, G. Dawson, A. Scott-Gillett, and R. A. Woodhouse.

ROYAL NAVY MEDICAL CLUB.—The annual dinner will be held at the Trocadero Restaurant, Piccadilly-circus, London, on Thursday, April 26th, at 7.30 P.M., for 8 P.M. Members who wish to be present should inform the hon. secretary of the club, Queen Anne's Chambers, Tothill-street, S.W. 1, not later than April 18th.

DENTAL OFFICERS IN THE ROYAL NAVY.—The following candidates were successful in a recent competition for commissions as dental officers in the Royal Navy: William Holgate, P. S. Turner, T. G. C. Emberson (Guy's), and A. A. Gardner (Dub.).

ROYAL ACADEMY OF MEDICINE IN IRELAND.—On March 22nd, in the Hall of the Royal College of Surgeons, Dublin, Colonel W. P. MacArthur delivered a lecture on Medical References in Pepys. The lecture, which dealt in some detail with the history of plague in England and Ireland culminating in the Great Plague of 1665, and with the prevalence of small-pox in the seventeenth century, was followed with great interest.

MAUDSLEY HOSPITAL.—A series of six clinical demonstrations of types of mental disease has been arranged by the London County Council. They will be given at the hospital, Denmark-hill, London, S.E., by the medical superintendent, Dr. Edward Mapother, on successive Wednesdays, at 2.30 P.M., beginning on April 25th. The series will be illustrated by numerous cases.

ROYAL SANITARY INSTITUTE.—A sessional meeting will be held on Friday, April 13th, at 5 P.M., in the Sessions House, Maidstone, when Dr. Alfred Greenwood will open a discussion on the Health of Hop-pickers and the Sanitation of Hop-pickers' Encampments. Prof. A. Bostock Hill will take the chair. On the following day visits will be paid to hop-pickers' encampments and hospitals. Those wishing to attend the discussion and visits should notify Dr. A. Greenwood, Sessions House, Maidstone, not later than April 6th.

THE death is announced, on March 26th, suddenly, at Eastbourne, of Dr. William Muir-Smith, J.P., at the age of 67. Dr. Muir-Smith was a native of Irvine, Ayrshire, and was educated at Glasgow University, qualifying in 1884. He was in practice at Bourton-on-the-Water before settling in Eastbourne, where he spent practically the whole of his professional life. Some twenty years ago he contributed an article to our columns, dealing with the ethical side of contract practice on lines which later became accepted policy.

WOLVERHAMPTON AND DISTRICT CLINICAL CLUB.—The first general meeting of this club was held at the General Hospital on Tuesday, March 20th, Dr. S. C. Dyke in the chair, and 36 members present. Discussion centred round the constitution of the club, which is designed to give members an opportunity for exchanging experiences and opinions in an informal way. The next meeting will be held at the General Hospital, Wolverhampton, on Tuesday, April 17th, at 8.30 P.M. The hon. secretary is Dr. R. L. Mackay, Woodfield-avenue, Wolverhampton.

EXTENSION OF ANCOATS HOSPITAL.—The annual report of this hospital proposes that advantage should be taken of its approaching centenary to appeal for help for extensions. The present 114 beds and single operating theatre are stated to be quite inadequate to an accident and urgency claim of over 20,000 cases per annum. On the analogy of the 118 voluntary hospitals reported upon by the British Red Cross Society the facilities should be treble what they are. It is hoped to raise at least £100,000 to provide new casualty, X ray, and massage departments, two operating theatres, a laundry, and the additional accommodation required for nurses and domestic staff.

ROAD ACCIDENTS AT LEEDS INFIRMARY.—At the annual meeting of this institution it was stated that last year over 1000 persons injured in motor accidents were treated at a cost of £4399, but that the total sum recovered from these patients was only £62.

LONDON HOMŒOPATHIC HOSPITAL.—At the annual meeting it was stated that last year 1793 in-patients and the "record" number of 14,643 out-patients were treated. Increased activity has, however, produced the usual result of a discrepancy between income and expenditure, and the accumulated deficits now reach nearly £20,000.

KING EDWARD'S HOSPITAL FUND.—The Earl of Iveagh has been appointed a member of the General Council, in succession to his father.—Mr. Eardley Holland has been appointed a member of the Distribution Committee in place of Sir Francis Champneys, who has retired from the committee, of which he has been a member for 18 years.

SHEFFIELD PENNY-IN-THE-POUND SCHEME.—Last year this scheme produced £111,285, and the total amount of money yielded by all the sources controlled by the Joint Hospitals Council was £116,554. Hitherto the scheme's best year was 1925, when £108,000 was collected. Since 1920 the number of beds in the Sheffield hospitals has been increased by 277, and the total is now 1046.

FRACTURE DEPARTMENT AT WOLVERHAMPTON.—The annual report of the Wolverhampton and Staffordshire Hospital announces that, in order to cope with the increasing number of fractures, it is intended to set up a fracture and orthopædic department on modern lines. It will be placed under the charge of Mr. Anthony Blackstock.

CITY OF LONDON MATERNITY HOSPITAL.—At the annual court of governors, the Lord Mayor of London, the president, laid stress upon the need of a new nurses' home, which will cost £30,000. In the antenatal work last year there were 6000 attendances as compared with 3726 two years ago. The hospital trained 36 medical practitioners and students, 67 midwives, and six maternity nurses.

SEAMEN'S HOSPITAL SOCIETY.—Having recently taken over the Alexandra Memorial Hospital at Marseilles the society now possesses seven establishments. Last year's income was £89,996, and the expenditure £82,978. A new pathological department is to be added to the extension of the Dreadnought Hospital at Greenwich, which needs a supply of radium, for the purchase of which £900 is still required.

Medical Diary.

Information to be included in this column should reach us in proper form on Tuesday, and cannot appear if it reaches us later than the first post on Wednesday morning.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY, April 3rd.—8.30 P.M., ORTHOPÆDICS. Paper: Dr. Charles Scudder (Boston, Mass.): The Treatment of Recent Fractures by Operation; to be followed by Sir Robert Jones, Prof. E. W. Hey Groves, Mr. H. A. T. Fairbank, and Mr. W. A. Cochrane.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham.

MONDAY, April 2nd.—2.30 to 5 P.M., Medical, Surgical, and Gynæcological Clinics. Operations.

TUESDAY.—2.30 to 5 P.M., Medical, Surgical, Throat, Nose and Ear Clinics. Operations.

WEDNESDAY.—2.30 to 5 P.M., Medical, Skin, and Eye Clinics. Operations.

THURSDAY.—11.30 A.M., Dental Clinics. 2.30 to 5 P.M., Medical, Surgical, and Ear, Nose and Throat Clinics. Operations.

On Monday and Wednesday, at 2.30 P.M., there will be demonstrations of Medical Cases by Dr. A. J. Whiting and Dr. J. B. Alexander, respectively.

WEST LONDON POST-GRADUATE COLLEGE, West London Hospital, Hammersmith.

MONDAY, April 2nd.—10 A.M., Dr. Dowling: Skin Department. 2 P.M., Dr. Trevor Davies: Gynæcological Department. 2 P.M., Dr. Ironside: Medical Out-patients.

TUESDAY.—10 A.M., Medical Registrar: Medical Wards. 2 P.M., Mr. Sinclair: Surgical Out-patients. 2 P.M., Mr. Hamblen Thomas: Throat, Nose, and Ear Department. 2 P.M., Mr. Addison: Operations.

WEDNESDAY.—10 A.M., Dr. Burnford: Medical Wards. 2 P.M., Mr. Tyrrell Gray: Operations. 2.30 P.M., Mr. Donald Armour: Surgical Wards.

THURSDAY.—10 A.M., Dr. Grainger Stewart: Neurological Department. 2 P.M., Mr. Simmonds: Surgical Out-patients. 3 P.M., Sir Henry Simson: Gynæcological Ward.

Daily, 10 A.M. to 5 P.M., In-patients, Out-patients, Operations, Special Departments, Anæsthetic and Operative Surgery Classes.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, W.C.

THURSDAY, April 5th.—4 P.M., Dr. Schlesinger: Some Complications of Acute Specific Fevers in Children.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY POST-GRADUATE COURSE ON CANCER.

WEDNESDAY, April 4th.—3.30 P.M. (in the Medical School, Leeds), Prof. G. E. Gask: Radium in the Treatment of Malignant Disease.

MANCHESTER ROYAL INFIRMARY.

TUESDAY, April 3rd.—4.15 P.M., Mr. E. D. Telford: Pseudo-Coxalgic and Allied Conditions.

ANCOATS HOSPITAL POST-GRADUATE LECTURES, Mill-street, Manchester.

THURSDAY, April 5th.—4.15 P.M., Mr. P. G. McEvedy: Treatment of Hernia.

Appointments.

KENNEDY, C., M.B., Ch.B. Edin., has been appointed Assistant Gynæcologist to the Deaconess Hospital, Edinburgh, and to the Leith Hospital.

PIERCE, W. J., M.B., Ch.B. Liverp., Junior Medical Officer to the Liverpool Open-air Hospital for Children, Leasowe.

WEATHERHEAD, A. G. N., M.B., Ch.B. Edin., Medical Officer to the Royal Residential Schools for the Deaf, Old Trafford, and to Henshaw's Institution for the Blind.

St. John's Hospital for Diseases of the Skin: CORSI, H., M.B., B.Chir. Camb., Senior Honorary Medical Registrar; and HARTSTON, L., M.B., B.S. Lond., Junior Honorary Medical Registrar.

Surgeons under the Factory and Workshop Acts: CLAPPERTON, T., M.B., Ch.B. Aberd. (Oakham); LAWSON, R., M.D., Ch.B. Edin. (Hipperholme, W. Riding); and O'REILLY, J. J., M.B., Ch.B. Belf. (Chepstow).

Vacancies.

For further information refer to the advertisement columns.

Bangor, Carnarvonshire and Anglesey Infirmary.—H.S. £200.

Belgrave Hospital for Children, Clapham-road, S.W.—H.S. and Asst. H.P. Each at rate of £100.

Burton-on-Trent Infirmary.—H.S. £150.

Cambridge, Addenbrooke's Hospital.—Res. Anæsthetist. At rate of £180.

Carlisle Non-Provident Dispensary.—Res. M.O. £250.

Derbyshire Royal Infirmary, Derby.—H.S., Asst. H.S., and Cas. O. Each £150.

Doncaster Royal Infirmary.—Third H.S. At rate of £150.

Dover, Royal Victoria Hospital.—H.S. £180.

Dreadnought Hospital, Greenwich.—Anæsthetist. 50 guineas. Also Surgeon in charge of Out-patients.

Exeter, Royal Devon and Exeter Hospital.—H.P. At rate of £130.

Farnborough, Bromley Union Institution.—Res. M.O. £800.

Galway University College.—Professorship of Therapeutics, &c. Also Midwifery. Each £308–£320.

Halifax Royal Infirmary.—Third H.S. At rate of £100.

Hampstead General and North West London Hospital, Haverstock Hill, N.W.—H.S. and H.P. Also Cas. M.O. Each at rate of £100.

Holborn and Finsbury Hospital, Archway-road, N.—Second Asst. M.O. £300.

Hôpital Français, 172, Shaftesbury-avenue, W.C.—Phys. to In-patients. Phys. to Out-patients. Also Jun. Res. M.O. £100.

Hospital for Consumption and Diseases of the Chest, Brompton, S.W.—H.P. £50 for six months.

Hospital for Epilepsy and Paralysis, Maida Vale, W.—Res. M.O. and H.P. At rate of £150 and £100 respectively.

Hospital for Sick Children, Great Ormond-street, W.C.—H.S., H.P., and Asst. Cas. O. Each £50.

Hospital for Women, Soho-square, W.—Asst. Anæsthetist.

Indian Medical Service.—Commissions.

Laboratories of Pathology and Public Health, 6, Harley-street, W.—Asst. Pathologist. £500.

Leigh Infirmary, Lancashire.—Res. H.S. At rate of £150.

Liverpool Eye and Ear Infirmary.—Third Hon. Anæsthetist.

London Fever Hospital, Islington, N.—Hon. S.

Lucknow University.—Professor of Anatomy. Rs.1450 per mensem.

Manor House Hospital, Golders Green, N.W.—H.S. At rate of £200.

Metropolitan Hospital, Kingsland-road, E.—Sen. H.P. and Sen. H.S., Jun. H.P. and Jun. H.S. Also two Cas. O.'s. Each at rate of £100.

Mildmay Mission Hospital, Austin-street, Bethnal Green, E.—Sen. Res. M.O. Also Asst. Cas. O. At rate of £140 and £100, respectively.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Cas. O. £150.

Ministry of Health, Whitehall, S.W.—Deputy Regional M.O. £800.

Norwich, Norfolk and Norwich Hospital.—Cas. O. and H.S. £120.

Paddington Green Children's Hospital, London, W.—H.P. and H.S. Each at rate of £150.

Preston, Lancs, County Mental Hospital, Whittingham.—Sixth Asst. M.O. £350.

Prince of Wales's General Hospital, Tottenham, N.—H.S.'s and H.P., also Jun. H.S. and Jun. H.P. At rate of £120 and £90 respectively.

Princess Louise Kensington Hospital for Children, North Kensington, W.—H.P. and H.S. At rate of £100 and £75 respectively.

Queen's Hospital for Children, Hackney-road, E.—P. in charge of Skin Dept.

Rhondda Urban District Council.—Asst. M.O. £600.

Royal National Orthopædic Hospital.—Med. Reg. £150.

St. Mary's Hospital for Women and Children, Plaistow, E.—Asst. Res. M.O. At rate of £130.

South Eastern Hospital for Children, Sydenham, S.E.—Asst. Res. M.O. At rate of £75.

Walsall County Borough.—Clin. Tuberculosis O., &c. £750.

Walsall General Hospital.—H.S. At rate of £125.

Walsall Poor-law Institution.—Res. M.O. £600.

Weston-super-Mare Hospital.—Res. M.O. £130.

The Chief Inspector of Factories announces a vacancy for a Certifying Factory Surgeon at Kingston (Surrey).

Births, Marriages, and Deaths.

BIRTHS.

REID.—On March 23rd, at Rodney-street, Liverpool, th wife of Andrew McKie Reid, *M.C.*, F.R.C.S., of a daughter.

MARRIAGES.

CLAYE—KNOWLES.—On March 26th, at S. Mary's Church, Garforth, Andrew Monyihan Claye, M.D. Leeds, M.R.C.S. Eng., to Marjorie Elaine Knowles, M.B. Leeds, M.R.C.S. Eng. (By Licence.)

MURRAY—CLARK.—On March 24th, at St. Barnabas' Church, Kensington, John Murray, O.B.E., M.B., C.M., of Llandrindod Wells, to Ethel Mary, daughter of the late George Miller, Esq., Newberries, Radlett, Herts.

NORMAN—DAVIES.—On March 22nd, at Llanishen Parish Church, Anthony Norman, M.B., B.S., to Muriel Davies, M.B., B.S., D.P.H., younger daughter of Mr. and Mrs. Morris J. Davies, Lake-road West, Cardiff.

DEATHS.

DAVISON.—On March 18th, at Bryanstone-road, Bournemouth, James Davison, M.D., in his 82nd year.

MUIR-SMITH.—On March 26th, suddenly, at Riversdale, 8, Upperton-road, Eastbourne, William Muir-Smith, M.B., C.M., J.P., aged 67.

MULLOCK.—On March 23rd, at a nursing home in Norwich, Richard Wilson Mullock, M.D., of Southwold, Suffolk.

PHILLIPS.—On March 23rd, at Harpur-place, Bedford, Francis Barclay Willmer Phillips, M.A., M.D. Oxf., B.Sc. Lond., D.P.H. Camb., Medical Officer of Health for Bedford, aged 75.

PLAYFAIR.—On March 25th, Hugh James Moore Playfair, M.D., F.R.C.P., F.R.C.S., Chevalier de la Légion d'Honneur, of Upper Brook-street, W., in his 64th year.

SEARSON.—On March 19th, James Searson, M.D., L.R.C.P.I., L.R.C.S.I., of Welbeck-street, W., in his 69th year.

STARK.—On March 18th, at Wanstead Park-avenue, E., Dr. Arthur Campbell Stark, aged 63.

WISE.—On March 23rd, at a nursing home in London, after a few days' illness, Alfred Thomas Tucker Wise, M.D., M.R.C.S., L.R.C.P., Swiss Federal Diploma in Medicine, of North Mills, Strete, Devon.

N.B.—A fee of 7s. 6d. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Comments, and Abstracts.

PHYSIOLOGICAL PERSONALITY.*

By Robert Hutchison, M.D. Edin., F.R.C.P. Lond.,
PHYSICIAN TO THE LONDON HOSPITAL.

By physiological personality I mean those slight differences in the working of the bodily machine which occur in different individuals, but which are within the limits of health. Differences in the structure and configuration of the machine—in the "order of architecture" to which it belongs to use Mercier's phrase—we are all familiar with and those constitute the anatomical personality or physique. The peculiarities of the physique and of the physiological personality together determine how the machine will behave in various circumstances—or, if you like, how it will react to the stresses of the environment—and may be spoken of as its "constitution," by which is really meant the sum total of its structure and working. In the same way we might speak in the case of a motor of its having a Rolls Royce or a Ford "constitution," meaning that it has a structure and mechanism peculiar to those makes. In some persons the constitution diverges so far from the mean as to induce a proclivity or predisposition to suffer from particular types of disease, and such a type of constitution may be called a "diathesis," and accordingly we hear of a "rheumatic" diathesis, of a "tuberculous" diathesis, and so forth, and these may be recognisable from the anatomical personality alone. To return to the simile of the motor we might in similar language describe a type of car which from its structure and working has a tendency to get over-heated as suffering from a "calorific" diathesis.

Again, just as the "constitution" of the bodily machine determines liability or otherwise to disease so, on the mental side, it determines "temperament" which is that part of the character which is dependent upon anatomical and physiological peculiarities of the individual and is unalterable; but of the relation of character to physiological personality I shall have something further to say later on.

Now, although we still sometimes hear a patient say that Dr. So-and-So "understands his constitution" there is no doubt that less importance is attached by the profession to differences in constitution than was once the case. As you are doubtless aware it was the fashion at one period in medical writings to describe four main types of constitution—the sanguine, lymphatic, bilious, and nervous, based mainly upon external differences in bodily appearance—i.e., upon anatomical personality. Gradually, however, these terms have disappeared from medical literature. Nor is it difficult to understand the reason for this. When physiology first began to be accurately studied, the methods employed were such as to reveal only the nature of the grosser processes and modes of working in which all human beings are alike, and it is only within recent times that they have become sufficiently delicate to distinguish the finer variations in these processes which may be met with in different individuals of apparently normal type. With the rise of an exact pathology, too, and a more accurate understanding of the immediate causes of disease attention came to be concentrated chiefly on the exciting agent in morbid processes to the neglect of the "soil" on which the disease is implanted. Here, also, there has been a decided reaction in the last few years.

I think, therefore, that one may profitably make the attempt to inquire into the question of constitutions, not from the external or anatomical point of view,[1] but by considering what are the possible variations in the mode of working of the machine which are yet within the limits of health—that is to say, into the essence of physiological personality.

It will be obvious that such variations may affect either the vital working of the machine as a whole—i.e., its metabolism, or they may be found in the functional capacity of its parts—i.e., the viscera.

Individual Variations in Metabolism.

There may be individual differences: (1) in the total amount or rate of tissue change in the body, or (2) in the nature of the by- or end-products of katabolism. The former one may speak of for convenience as quantitative and the latter as qualitative differences.

(1) That the rate of metabolism, and in consequence the total turnover of material, varies in different individuals admits of no doubt. In part such differences may be explained by variations in anatomical personality—i.e., by differences in shape and build.[2] The larger the surface of the body relative to its bulk the greater is the amount of heat loss and the greater therefore the demand for heat production in the chemical regulation of the body temperature. It is for this reason that tall men (who have relatively a large surface) have difficulty in storing fat. Children, also, who have a large surface in proportion to their bulk, have an active metabolism for the same cause. Apart from gross anatomical differences in build and shape, however, there can be no doubt that the "make-up" of the body varies greatly in different individuals and has a profound influence upon general metabolism. Where the muscles are large and well developed, for instance, the amount of oxidation is certainly greater than in cases in which a large mass of the body is composed of a comparatively inert material such as fat.

The amount of fluid in the tissues, too, probably exerts an influence, and there is no question that this varies not only in different individuals but in the same individual at different times.[3] In cases of cachexia and in old age it is well known that fluid in the body is increased at the expense of fat, but apart from such instances as these, everyone must have seen patients who could not be described as œdematous but who have yet lost an enormous amount of weight after the establishment of a profuse diuresis. It seems certain, indeed, that individual differences in the weight of the body are more often dependent upon fluctuations in the amount of fluid it contains than is generally realised, and it is inconceivable that such differences should be without effect upon metabolism, whilst there is some clinical reason for believing that they also influence the capacity for resistance to acute infections. The drier the body the greater the resistance appears to be. In other cases the greater activity of metabolism is due probably to an unusul degree of vital activity in the cells composing the body. Young cells have more vitality than old, and as age increases the physiological personality tends to change in a direction of a slowing of metabolism.

A very important influence on the general rate of metabolism is certainly exerted by "internal secretions," particularly by the thyroid secretion which is the most potent stimulant of general metabolism we know, although other internal secretions, especially those of the reproductive organs, also seem to exert a profound effect. The powerful influence of the thyroid is shown in the general diminution of oxidation in cases of myxœdema, and it is probable that there are very many cases in which the thyroid secretion, though not altogether absent, is being produced in insufficient amount. It is not unlikely that the tendency to put on fat after middle life which so many people exhibit is to be attributed to a waning activity of the thyroid, and cases of so-called "endogenous" obesity (i.e., those in which fat is stored up even on a diet of low caloric value) may have a similar origin.

There is yet another factor in producing variation in general metabolism which cannot be ignored, and that is the influence of the nervous system. It seems clear that impulses emanating from the central nervous system exercise a control over the nutrition of the tissues possibly by restraining katabolism. The best example of this is seen in the rapid wasting of muscles which are cut off from their connexion with the spinal cord, and if this "grip" of the nervous system on the tissues varies in different individuals, as it may do, metabolism and nutrition are bound to be affected. In all these ways, then, and doubtless in others, the general rate or amount of metabolism may vary and the physiological personality or constitution of the individual be influenced.

How differences in "constitution" which result from these variations in metabolism affect health or individual liability and reaction to disease we do not by any means fully know, but it is certain that they cannot be left out of

---

* A lecture given to the Cambridge University Medical Society, February, 1928.

[1] An elaborate study of the relationship of anatomical personality (human morphology) and disease has been begun by Dr. George Draper in America (Human Constitution. London and Philadelphia: W. B. Saunders Company. 1924), mainly on anthropometrical lines. He proposes to extend his investigations later to the study of physiological, immunological, and psychological characteristics.

[2] Dr. C. J. Macalister has made the interesting suggestion (THE LANCET, 1924, ii., 533) that some metabolic peculiarities in individuals may be due to a partial reversion to an ancestral type of metabolism—carnivorous or herbivorous, as the case may be.

[3] Czerny applies the term "hydropic constitution" to the tendency shown by some children to hold back fluid in the tissues; and MacAuliffe suggests that, since biochemically all living things are colloidal structures, their form is perhaps determined by their power of water-absorption and retention, or, as he calls it, "hydrophylly." Those creatures that are built on ample lines and are cubic in form may be regarded as positively hydrophyllic, whereas the angular and lithe are negatively hydrophyllic. (E. Miller.)

account. On the whole, one might expect that an exceptionally rapid metabolism would lead to impairment of nutrition with all its consequences, whilst an unusually slow rate of tissue change—a retardation of metabolism as Bouchard called it—would favour the production of obesity with all its disadvantages, and might induce also the imperfect carrying out of the final stages in the disintegration of some of the products of metabolism with the liberation of abnormal constituents into the blood stream which in their turn might result in various forms of disease such as gout. Whether variations in the general rate of metabolism affect the power of withstanding disease it is difficult to say, but it seems reasonable to suppose that an active metabolism makes for vigour and resistance. It is interesting in this connexion to remember that part at least of the beneficial effects of "open-air" treatment is now ascribed to the stimulation of general metabolism which it brings about.

Apart from variations in total metabolic activity, there exist undoubtedly what one may speak of as qualitative differences in the metabolic processes of the body. As Sir Archibald Garrod, who has devoted a great deal of attention to this subject, has pointed out, it is not likely that alternative paths exist for katabolism, but when abnormal end-products appear it is more probable that they simply represent an arrest at some point on the normal downward stage. That an inability completely to carry out certain metabolic processes exists in some individuals is shown by the examples of alkaptonuria, cystinuria, and pentosuria, and doubtless there are kindred abnormalities which we have not yet learnt to recognise. If it be the case, as some believe, that an inability to carry out fully the katabolism of purins is a factor in the production of gout, we have an example of how a variation in physiological personality may actually produce disease, and perhaps an inherent disability in dealing with sugar—hypoglycopyresis as Dr. O. Leyton has called it—may be the foundation of the family tendency to diabetes so often met with. Such qualitative differences in metabolism may also be at the root of idiosyncrasies to certain foods and of the varying reaction in individuals to drugs. There is room, too, for wide differences in chemical constitution in different individuals. The possible variations in the exact make-up of the protein molecule, for instance, are almost infinite and may account for such phenomena as protein sensitiveness and an asthmatic diathesis. The reaction of the body may also vary, and Dr. H. A. Ellis has even made the interesting suggestion [4] that all people can be divided into acid, normal and alkaline constitutions, and that whether an individual be what we call an "acid" or an "alkali" controls both his health and temperament and determines to some extent his liability to disease; an "alkaline" constitution being part of the tuberculous diathesis whilst an acid one predispose to gout. This suggestion certainly opens up possibilities of the most fruitful lines of inquiry.

Physiological personality, however, depends not merely upon the working of the machine as a whole, but upon variations in the efficiency of its component parts, the viscera. I have not time, even if I had the knowledge, to deal fully with this aspect of the subject, but we may glance briefly at some of the factors which may underlie variations in the functional activity of the chief visceral systems in different individuals.

The Digestive Organs.—At the outset we have to consider the possibility that in some persons the digestive apparatus is really too small or ill-developed to supply fully the needs of the tissues in the way of nutrition. I am not aware whether this possibility has ever been the subject of accurate investigation, but we know clinically that persons in whom the lower thorax is contracted so that there is little room for the stomach and liver are peculiarly prone to suffer from functional digestive disorders. In such subjects the abdominal organs are often unduly mobile from maldevelopment of the fixing bands and ligaments with the result that visceroptosis with all its attendant train of disabilities readily ensues. This is an essential part of the "morbus asthenicus," a constitutional peculiarity which almost amounts to a diathesis, predisposing as it does to functional dyspepsia and to neurasthenia. It will be found, I think, that a more or less sheltered life is generally instinctively chosen by such persons, and that on the temperamental side they are apt to suffer from a feeling of "insufficiency." Dr. Parkes Weber,[5] in a paper on Automatic Vital Safety-Valve Actions and Reactions, speaks of such persons as being of a "low-pressure type," and considers that they have a safety-valve which comes into action at low pressure in the form of fatigue, dyspepsia, &c. The robust, full-blooded individual, on the other hand, belongs to the "high-pressure" type and *his* safety-valve only comes into action at high pressure—for example, in the form of hæmorrhages.

Apart from this general disability, which is really a fault of physique, we know quite certainly that in regard to those functions of the stomach which permit of accurate investigation great individual differences appear even within the limits of health. In the case of secretion, for instance, investigation shows that the production of hydrochloric acid is higher in some healthy persons than in others, and that it is higher in the young than in the old. Where the variation is in the direction of an excessive production we have a physiological personality which, as Hurst has pointed out, is certainly predisposed to suffer from a specific form of disease—namely, duodenal ulcer. Take again the other great function of the stomach, the exhibition of muscular tone. Here, also, there are undoubtedly individual variations in efficiency which are probably inborn and persist throughout life. Some people, as is well known, always have splashy stomachs and readily suffer from "slow" digestion with flatulence and other signs of disordered function. Such persons, indeed, make up the larger proportion of habitual functional "dyspetics." Whether this defect of the muscular function is due to congenital feebleness of the muscle itself, to an impaired elasticity, to a defective supply of nervous energy, or of an adrenal hormone is not known, but the marked aggravation of the disorder by fatigue, either mental or physical, points rather to a nervous basis. That, however, is immaterial. The main point is that here again we have a peculiarity of physiological personality which may greatly affect health and liability to disease, and, as we shall see later, the mental characteristics of the individual as well. On the other hand, there may be an inborn exaggeration of tone in the stomach which often accompanies an excess of acidity, the two constituting together the ulcer diathesis.

Passing from the stomach to the other great digestive organ, the pancreas, we find ourselves hampered in studying physiological variations in its activity by the difficulty of investigating the composition and amount of the normal secretion. I would suggest, however, that differences in digestive capacity in different individuals may sometimes be due to differences in the amount or composition of the pancreatic juice. Especially does it seem likely that the congenital inability to digest fats easily may have some such cause. There can be no question that nutrition may be greatly impeded particularly in infancy by this inability and the liability to certain diseases, and in particular to tuberculosis, increased by it. In extreme cases of congenital defect of pancreatic secretion we know that the whole nutrition and development of the body is interfered with and a condition of infantilism may result.

Of variations in intestinal digestion we know even less than we do of the pancreatic, but as regards the other great intestinal function-motility, there seems to be no doubt that great individual differences exist, and that in some persons there is an inborn deficiency of intestinal tone and peristaltic activity which predisposes to constipation with all its consequences, physical and mental. Here, just as in the case of the stomach, it is uncertain how far the deficiency is directly due to the intestinal musculature and how far it is the consequence of defective innervation. Peculiarities of anatomical personality due to differences in the length and fixation of the colon may also contribute largely to such defects of action, as Mr. G. E. Waugh has pointed out.

But of all the abdominal organs it is the liver variations in whose efficiency and activity one might expect to produce the greatest effect on constitution and character seeing that it touches organic life at so many points. It will be sufficient to remind you that the liver is both a glycogen and a fat former, that it removes the disintegration products of the red blood corpuscles, that it is concerned in the final stages of proteolysis, and that it acts as a "portal sentinel," preventing to some extent the passage of injurious substances from the intestine into the general circulation. The efficiency or otherwise with which it discharges these functions is bound to have a far-reaching influence on physiological personality. It has often been suggested that there is such a thing as a congenital "hepatic inadequacy" affecting either the capacity of the liver as a whole (possibly from its being too small for the needs of the organism) or involving one or more of its special functions. The validity of such a suggestion is very difficult to determine, but there is a good deal of clinical evidence in favour of the view that the gouty diathesis may depend in the last resort upon a relative incapacity on the part of the liver, and that liability to such conditions as "bilious attacks," migraine, and cyclical vomiting may have a similar origin. The recent introduction of tests for estimating the efficiency of the liver may enable us to acquire a further insight into individual variations in function and into the so-called hepatic inadequacy.

The Circulatory System.

That the efficiency of the heart is greater in some individuals than in others is certain. It has long been known, for instance, that the size of the organ is by no means the same even in normal subjects, and Dreyer has shown that variations in this respect are related to differences in the extent of body surface. The larger the surface area the greater is the size of the heart for, as we have already seen in another connexion, a large surface means a great heat loss, and this in its turn necessitates an active circulation and throws more work upon the heart. This is really a question of anatomical personality, but it is reasonable to suppose that a heart which, even to meet the normal physiological requirements of the body, requires to be above the average in size must have less margin for hypertrophy to meet unusual exigencies of stress or disease. Hence in this respect, just as in the maintenance of body temperature and nutrition, the possession of a relatively large body surface is a handicap and a source of weakness in the "constitution." Apart from the question of size there is scope for considerable variation in the various physiological properties of the heart muscle—in excitability, conductivity, contractility, and tonicity—and there is room, too, for much latitude in the degree of control exercised by the nervous system over the organ.

Although we are not yet in a position to test the efficiency of each function of the heart in any given individual, there is ample evidence of considerable variations in their working, and it is not surprising that scarcely two individuals give identical electrocardiograms. Individual differences in the frequency and force of the pulse and the occasional occurrence of habitual irregularity of the heart throughout life are further examples of such evidence. It is common knowledge, too, that the degree of cardiac acceleration in response to the same amount of physical effort and the subsequent decline of rate vary materially in different individuals. This "lability" of the heart's action may be regarded as a sign of a neurotic constitution. It is when the heart is subjected to unusual stress and strain, however, that inborn variations in its efficiency become manifest. One person, for instance, may pass through an excessive physical effort with impunity which in another induces serious distress. Here we are probably dealing with congenital differences in tonicity which we have already seen play such a large part in the relative efficiency of the stomach and intestine, but whether these differences are structural—i.e., essentially anatomical (due, for instance, to a deficiency of elastic tissue) or "vital" in origin we are not yet able to say. That the efficiency of the myocardium is a large factor in physiological personality, however, is certain, and it determines to a great extent the capacity of an individual to stand physical strain or the stress of an acute illness, and it will be found, I think, that people who are handicapped by these congenitally inefficient hearts instinctively avoid violent exertion. A large number of the recruits who broke down in the war with heart troubles (D.A.H., and so forth) probably belonged to this class. Like the heart the blood-vessels, too, exhibit a varying capacity to stand strain and wear and tear which is probably due to inborn differences in the elasticity of the vessel wall—to the quality of the "tubing" as Osler put it. How greatly such differences affect constitution is recognised in the saying that a man is as old as his arteries.

Variations in blood pressure in different individuals also play a large part in determining differences in constitution especially as life advances. The tendency to develop high tension in later life which is characteristic of some individuals and even of families is probably not due to any peculiarity of the vessels themselves, but a secondary result either of some metabolic error, of "renal inadequacy," or possibly, of over-secretion on the part of the suprarenals, but however brought about it is a constitutional peculiarity which it is of the greatest importance for the physician to recognise. It has been described by Hurst as a hyperpietic diathesis.

Lastly, there seem to be considerable differences in the vasomotor control of the blood-vessels in different individuals which determine the existence of a "good or "bad" circulation with consequent varying capacity to stand the effects of cold and varying predisposition to such disorders as chilblains, Raynaud's disease, migraine, &c. When the control of the splanchnic system is inherently defective, the blood pressure varies greatly with the position of the body, fatigue seems to be badly borne, and pooling of the blood in the splanchnic area with consequent faintness is readily induced. Differences in vasomotor control may also perhaps be at the root of the varying susceptibility of different people to barometric pressure and electrical conditions of the atmosphere—to "weather" in fact.

The Blood.

Individual peculiarities of the blood have not been much studied, but several are at least conceivable. In the first place, the total volume of the blood may vary in the direction of true plethora—the sanguine temperament of the older writers. The number of red and white cells per cubic millimetre, is also to some extent a variable quantity, and so, within certain limits, is the relative proportion of the different white cells and the percentage of hæmoglobin, some people having all their lives a slightly chlorotic blood. The destructibility of the red cells, too, is in all probability different in different persons. In extreme cases, as in family jaundice, there is such an unusual inborn fragility of the red corpuscles that visible pathological effects are produced, but such a condition is compatible with long life and comparative health, and in its slight degrees might remain unnoticed though it would certainly predispose to anæmia. Little as we know of these grosser histological variations in the blood we know even less of individual differences in its chemical composition, although the possibilities in this direction are almost infinite, for it must be remembered that all personal peculiarities of metabolism must be reflected in it. Recent investigations, however, have shown that while the total nitrogen, non-protein nitrogen, and sugar in the blood vary in the same individual from week to week there is a tendency for the level of these variations to be individual and the sum of the average deviations of the constituents may be an index of the metabolic stability of that person. The absolute amount of creatinine also is a constant for the individual.

In hæmophilia, again, there appears to be an inborn defect in the prothrombin, and it is possible that lesser degrees of this may determine a greater or lesser tendency to bleed easily in normal persons. Further, the amount of cholesterol in the blood seems to vary in different people, and Parkes Weber has suggested that there may be a constitutional hyper- or hypo-cholesterolæmia which may determine the individual's liability or otherwise to suffer from certain diseases, hyper-cholesterolæmia being a part of the gall-stone "diathesis"—i.e., that sort of constitution which predisposes the person to suffer from gall-stones and (probably) from other disorders as well. Lastly, there can be no doubt that there are wide individual variations in natural immunity of which the blood is the vehicle. This has been shown, amongst other ways, by the results of the Schick test for diphtheria.

Respiratory System.

The chief individual variations in the respiratory system that we can recognise are differences (1) in the vital capacity, and (2) in the elasticity of the lungs. The former is capable of exact measurement and has long been known to vary greatly in different persons depending upon the size and shape of the chest and the elasticity of its wall. Defect of vital capacity is well recognised as a serious constitutional handicap, lessening fitness for undergoing some forms of exertion and predisposing to pulmonary tuberculosis. It is really, however, an affair of physique. An inborn deficiency in the elasticity of the lungs or an undue tendency for impairment of elasticity to set in as age advances seems to play a part in the production of emphysema and may seriously interfere with activity and ultimately shorten life. It may be compared to the congenital deficiency of elasticity and "wearing" power in the walls of the blood-vessels to which reference has already been made, and with which indeed it is often associated. The excitability of the respiratory centre seems also to vary in different persons, and Hurst suggests that an inborn exaggerated irritability of the bronchial centres is an essential element in the "asthmatic diathesis."

The Excretory Organs.

Of individual variations in activity of the organs of excretion—the skin and kidneys—and of the degree to which such variations may affect physiological personality we know very little. It is true that the texture and so forth of the skin may determine its liability to disease, but that is really a matter of anatomical personality. We know that the cutaneous secretory activity varies greatly in different individuals, but the effects of this on constitution and temperament are not so obvious. Persons with sluggish skins are, one should suppose, constitutionally unsuited to live in tropical climates, and it has also been suggested that habitual inactivity of the skin throws more work upon the kidneys and constitutes to some degree a "renal diathesis." All this, however, is rather speculative.

Variations in the perfection of the kidney functions must be of much more significance than kindred variations in cutaneous efficiency; but of these also we know very little. We know, however, that the acidity of the urine varies greatly in different persons partly as a reflection of metabolic peculiarities and partly as the result of variations in concentration which are dependent upon the greater or lesser functional activity of the skin, and it has been shown by Osman that a high acidity of the urine predisposes to the development of nephritis whilst it also favours the appearance of some forms of calculus. The application of the now existing tests for renal efficiency to large numbers

of "normal" individuals should throw light on physiological variations in kidney function, and enable us better to recognise constitutional peculiarities and weaknesses which may render the subject of them liable to disease.

The Ductless Glands.

Variations in activity of the different ductless glands no doubt play a large part in determining both anatomical and physiological personality, but so much has been written on this subject in recent years that I need not refer to it at any length. We know, for example, how variations in pituitary activity may influence growth and fatness, how the thyroid affects metabolism, how the parathyroid regulates the calcium exchanges and through these the irritability of the nervous system, how the adrenals and gonads determine the degree of virility, and so on. There can be no doubt, too, that there is room even within the limits of health for wide variations in the activity of individual endocrines, and that such variations must profoundly affect "constitution." None the less I think the tendency at present is to exaggerate the part played by the ductless glands, or perhaps I should say to assign to them an independence and initiative which they may not possess. To take an example: adrenal dominance is said to produce an individual of the virile, "live-wire," "quick in the uptake" type. Even granted that such individuals have unusually potent adrenals—and this cannot be said to be really proven—the question arises, is the adrenal dominance primary or is the overactivity of the gland determined by the nervous system?

Which is master, the endocrines or the brain? This question is really fundamental, for it applies not only to the relation between the nervous system and the endocrines but to the relation between the nervous system and the functional activity of all the viscera. It is possible, in short, that in the last resort most differences in *physiological* personality are nervous in origin, even although gross disease in a ductless gland may produce a primary but pathological change in the constitution. In health, in a word, the endocrines are perhaps the servants of the central nervous system: if they take command disease results. To this point I shall return again later.

The Nervous System.

That there must be great variations in the working of the nervous system is obvious from the striking differences in intellectual capacity in different individuals, and some of these variations are capable of exact measurement in the psychological laboratory. Variations in attention, memory, and reaction time are examples, although these affect character and intellect more than constitution. There are also differences in the "rhythm" of the motor processes, for instance the rate of walking, or of performing muscular acts natural to any given individual. These probably depend upon the "neuronic patterns" peculiar to the particular brain. Berry, in a paper on the Physical Basis of Social Inefficiency,[6] points out that the most superficial layer of cortical neurons is the latest to appear in evolution and that its depth varies greatly in different individuals. He considers that social efficiency depends in great measure on the degree of its development. "The problem of the range of variation and of the limits of normality," he says, "is an extremely important one in all biological processes and does not appear to be fully realised by the medical profession"

From the point of view of "constitution," however, one of the most important differences affecting the nervous system is what one may speak of as "fatiguability" or liability to exhaustion of function, which perhaps depends upon inherent stability or otherwise of the molecules of the nerve cells. A stable nervous system confers vigour upon the constitution whereas one which is easily fatigued predisposes to neurasthenia and functional disorders, although not, perhaps, to serious disease. There seem, also, to be degrees in the efficiency of the barrier which the nervous system sets between conscious life and that of the viscera, a low degree of such efficiency disposing to hysteria and psychasthenia.

It must be remembered, further, that in consequence of the control which it exerts over the viscera and possibly, also, over the nutritive processes, and in virtue of its integrative functions largely exercised through the endocrine system, the nervous system may be responsible for variations in physiological personality which are not at first sight likely to be attributed to it, as it acts indirectly by affecting nutrition, the functions of the heart and stomach, the blood pressure, and so on. As is well known, Dr. Eppinger and Dr. Hess originated the theory, which has since met with pretty wide acceptance, that the relative degree of control or influence of the vagal and of the sympathetic parts of the vegetative nervous system differs in different individuals, and that people may be roughly divided into vagotonics and sympathicotonics according to which nerve influence preponderates in their visceral control, vagotony being regarded as a form of constitutional inferiority.[7] There can be little doubt, I think, that this conception has been overdone and has been made to cover too wide a clinical field, but there is equally little doubt that "there is something in it," and that some facts of physiological personality may find in it their explanation. In the long run, perhaps, all variations in visceral function in different individuals which cannot be attributed to actual differences in structure may really be due to variations in nervous control. From this point of view the ultimate seat of physiological personality would be in the central nervous system. This need not be surprising if one remembers that the human central nervous system is the last product of animal evolution, and that variations in it are necessary in order to afford an opportunity for the play of natural selection.

We may now pass on to consider the ways in which physiological personality may determine "temperament" and character.

Influence of Physiological Personality on Character.

There can be no doubt that a man's character is largely dependent upon his physical constitution. This is certainly the case so far at least as several important elements of character are concerned, such as energy, courage, vivacity, and good temper, although as regards some of the finer elements, sympathy, sincerity, and so forth, the physical basis may not be so obvious. "Yet it does appear to me" said Sir Walter Scott, "that high and independent feelings are naturally though not uniformly or inseparably connected with bodily advantages. Strong men are usually good-humoured, and active men often display the same elasticity of mind as of body," and, to quote Mr. H. G. Wells, it may be that, "even the capacity for friendship is a question of physique."

Much might be said even of the influence of gross anatomical peculiarities upon character. What, for instance, is the effect of stature upon mental traits? Is the big man more equable and large minded, less excitable, fussy and self-assertive than the smaller man? Or was Bacon right when he said, "that Nature did never put her precious jewels into a garret four stories high and therefore exceeding tall men have ever empty heads," or quaint Thomas Fuller, when he expressed the same idea in very similar language, "Often the cock loft is empty in those whom Nature hath built many stories high." ? I hope not. Or had George Eliot any reason for her belief that red hair and brains never go together?

Herbert Spencer, in an interesting chapter of his Autobiography, ventures the opinion that much might be said about the mental effects of bodily deformity. One, he suggests, who knows that he is looked upon by others with disfavour or pity cannot help being in some measure soured, or if his deformity is of such a nature that he cannot join in the pursuits of normal men he may become the prey of envy. In present-day language he is said to suffer from an "inferiority complex." Again, is shyness not often the consciousness of some physical shortcoming, such, for example, as a pronounced squint or stammer? One might elaborate the argument at length, but we are concerned at the moment more with the influence of physiological than of anatomical personality on character, and it is this aspect of the subject that I wish now to consider.[8]

[6] Brit. Med. Jour., 1921, ii., 72.

[7] According to Eppinger and Hess, the vagotonics are tall, thin, and angular, with a tendency to sweaty and greasy skins, acneiform eruptions, cold extremities, and mental hebetude. Sympathicotonics, on the other hand, have dry skins, prominent eyes, and dilated pupils. They are less torpid than the vagotonics, and in extreme cases are given to excessive activity. The activity of the thyroid and suprarenal systems being heightened there is a more rapid response to external demands than in the vagotonics. Most persons, of course, present a balance between sympathicotonia and vagotonia, the two systems being in antagonism. Apart, also, from complete types of the two (which some authorities deny to exist at all) there is no doubt that the same organ may in different persons be predominatingly under vagus or sympathetic influence respectively, and that the liability of the organ to functional disorders may depend upon which influence preponderates.

[8] An elaborate study of the relation of anatomical personality to character has been published by Kretschmer (Physique and Character. Kegan Paul. 1925). He describes three leading types of physique, the asthenic, the pyknic, and the athletic, and attempts to correlate these with two main types of temperament, the cyclothymic—characteristic of the pyknics—and the schizothymic which prevails in the asthenic and athletic anatomical types. The cyclothymes are the ego-centrifugal; the schizothymes are ego-centripetals with a great disparity between the life of thought and that of feeling. From the psychiatric point of view the pyknics make up most of the manic-depressives; the asthenics and athletics most of the schizophrenics. Kretschmer's study is interesting, but it is based on a limited material observed amongst the insane, and many of his conclusions and distinctions seem far-fetched and artificial, whilst his terminology is needlessly obscure.

Let us look first at the temperamental influence of different types of metabolism. Just as a large total metabolic turnover indicates a high degree of vitality of the cells so also it probably predisposes to a high degree of mental energy. One has merely to consider the mental sluggishness of the subject of myxœdema—an extreme example of abnormally slowed metabolism—to be convinced of this. An active metabolism, in fact, seems to be associated with energy of will, high animal spirits and restlessness, whilst a slow metabolism goes with the reverse qualities. Again, the type of metabolism which predisposes to gout—the "acid" type of Ellis—goes often with a forceful and irritable character and high intellectual capacity. Hence gout has been described as "dominus morborum et morbus dominorum"—whilst the type predisposed to tuberculosis—the "alkaline" type—is accompanied by an imaginative and emotional—in a word by the "artistic" temperament.

Close, however, as the relation between metabolic type and temperament no doubt is, the relation between visceral function and character is probably even closer. As Herbert Spencer said: "Mind is not as deep as the brain only, but is, in a sense, as deep as the viscera." Feeling-tone, a sensation of well- or ill-being, of exaltation or depression, depends largely upon sensations derived from the activity of the viscera, which sensations, however, are normally outside consciousness except for the feeling-tone they engender. (Head.)

The abdominal viscera seem to be of predominant importance in this respect. Congenital feebleness of the digestive apparatus may lessen mental energy or at least impair cheerfulness and sociability. Dysentery saps the courage of an army, and as that wise physician and philosopher, John Locke, said, "People who have relaxed bowels have seldom strong thoughts." The relation of the abdominal visceral functions to mental and emotional states is so well recognised popularly as to have become proverbial. Thus we speak of a person as having "no stomach" for a thing, meaning that he lacks courage for it, or, more colloquially, he is said to be lacking in "guts." "Girding up the loins" is synonymous with screwing courage to the sticking place, whilst the mental depression associated with defective action of the liver is recognised in the well-known facetious reply to the old question, Is life worth living?—"it depends on the liver."

Peculiarities in the working of the circulatory apparatus might be expected to influence temperament by affecting the circulation through the brain. Oliver Wendell Holmes said, that "courage was an affair of the diameter of the carotid arteries," and anything which impedes the flow of blood to the brain seems to lessen it, thus the hunting man with early cerebral atheroma begins to "funk" his fences whilst the financier loses nerve for his speculations. The delirium that accompanies a failing heart is, as Head points out, an extreme example of a mental change dependent directly on altered vascular conditions. On the other hand, so good an observer as Sir William Broadbent found no constant relation between the pulse and temperament. "Speaking generally," he wrote, "I have found physical strength, energy and endurance, impartially associated with small low tension pulse, and with large arteries and high tension, and the reverse. I can say the same of intellect, perseverance, courage and force of character generally: they appear to be absolutely independent of circulatory conditions."

Imperfect purification of the blood from defective action of the kidneys may also influence the brain and through that the whole temperament. We see this in an extreme degree in cases of uræmia, and in a lesser measure it may occur even in conditions short of disease. As Dr. Harry Campbell has said, "If two persons were to exchange bloods they would, in large measure, exchange temperaments."

Fully to consider the relation between variations in the functional activity of the nervous system and character would take us too far afield and would involve a discussion of the whole relationship of mind and body. How profoundly, however, an alteration in the state of the nervous system affects temperament may be seen in the changed personality witnessed in neurasthenia, and in general paralysis or even more dramatically in the deterioration of the moral character which sometimes follows an attack of lethargic encephalitis. A difference in the rate of the nervous processes, too, must influence capacity both in the physical sphere as in "striking" a fish and in the purely mental domain as in grasping an opportunity. Again, a predominance of sympathetic control is believed to produce an energetic, adaptable type of character, whereas when the para-sympathetic has the upper hand a slower and more sluggish type results. It may be contended,[9] however, and I think with truth, that it is chiefly the intellectual side of character which is directly affected by nervous action and that its finer moral qualities are largely independent of the physiological personality.

Nor can we leave out of our survey the influence on temperament of variations in "endocrine personality," but our ignorance here is so great that it is unwise to be dogmatic. There can be no doubt, however, that variations in the activity of the organs of internal secretion may exert a profound influence on character, though it is probably an exaggeration to speak of them as Berman does as "The Glands regulating Personality," or like another author, as "The Glands of Destiny," and to assume that all temperamental differences can be traced back to this origin.[10]

We must beware of too mechanistic a view. It may be true that the thyroid is our carburetter, the adrenals our magneto, and the central nervous system our steering-gear, but there is a god in the car all the same, call it "will," "psyche," "soul," or what you please, who has a large measure of control over the whole mechanism and upon whose nature much the most important part of character depends.

In conclusion, if there be any truth in what has been said, its recognition should at least save us from what someone has spoken of as "the commonest fault of the prescriber—the easy-going habit of assuming that every one is alike." It should convince us that although men may be born free, as the preamble to the American Constitution states, yet they are not born in any physiological sense "equal"; that man is not one but a diversity of creatures. It should impress upon us the futility of trying to lay down "rules of health" applicable to everyone and the duty of teaching each of our patients how to manage his own machine so as to get the best out of it, remembering that there are self-made men physically as well as financially. Finally, it should uplift us as doctors with the thought that in so far as we are able to modify or correct defects in the physiological personality we may influence character, and in so doing become active co-workers with those moral and spiritual forces which mould mankind.

[9] William James was of opinion that where the character, as distinguished from the intellect, is concerned, the causes of human diversity lie chiefly in differing susceptibilities of emotional excitement and in the different impulses and inhibitions which these bring in their train. It may well be, however, that emotional susceptibility depends in its turn on the character and balance of the endocrine and vegetative nervous systems.

[10] Over-action of the suprarenals, for instance, seems to be associated with a virile character, but with a dominance of fear in the temperament and a liability to the occurrence of phobias and anxiety states. Under-activity, on the other hand, is associated with a general feebleness of character. An active thyroid is believed to conduce to creative activity and to be the basis of what is called the "artistic" temperament, whilst pituitary activity and musical or mathematical ability are said to go together. Much of this, however, is highly speculative.

THE JERUSALEM ACADEMY OF MEDICINE.

THE Academy of Medicine of Jerusalem is a society of medical practitioners formed to unite, on common basis of scientific interests, professional men who might otherwise remain far apart. The 45 members speak at least ten different languages, and come from many different training schools. The successful publication of the first annual bulletin is proof, therefore, of a triumph of tact and perseverance over many obstacles. It contains a brief résumé of the year's proceedings, which included 11 scientific meetings and a dinner. Among the papers read at these meetings and published here in abstract were several on Typhoid in Palestine, one on Blindness in Palestine, and others on the Plague, Goitre, and Collapse Therapy in Pulmonary Tuberculosis. We wish the Academy of Medicine in Jerusalem every success.

A YEAR BOOK OF LEARNED SOCIETIES.

Messrs. Charles Griffin and Co. have just issued for the forty-fourth year in succession a Year Book of the Scientific and Learned Societies of Great Britain and Ireland. This is a record, compiled from official sources, of the work done in science, literature and art during the session 1926–27 by numerous societies and Government institutions. In the preface emphasis is justly laid on the fact that the prosperity of a nation is largely based on the labour of its scientific investigators, whether in the matter of production or of the health of the producers. The year book affords striking testimony of the amount and variety of original scientific work put forth within a twelvemonth. Section XIV. of the year book, which is devoted to Medicine, contains more than 50 pages, within which are enumerated the publications of the Ministry of Health and of the Medical Research Council, and the titles of papers read at the principal medical societies. There is also a list of the smaller medical societies with names of president and secretary attached. The year book is of a type of publication which accumulates value from year to year. The price is 18s.

SYPHILIS AND VENEREAL DISEASES.

by C. F. MARSHALL, M.Sc., M.D., F.R.C.S. Eng., and E. G. FFRENCH, M.D., F.R.C.S. Edin., M.R.C.P. Lond., Lieut.-Col. R.A.M.C. (Ret.), late O.C. Military Hospital, Rochester Row, S.W.

Fourth Edition, revised and illustrated with 7 Coloured Plates and numerous Figures. Price 15s.

London: Baillière, Tindall & Cox, 8, Henrietta-st., Covent Garden.

Second Edition **STEVENS' PRACTICE OF MEDICINE** *Thoroughly Revised*

The advances that have been made in Internal Medicine since the appearance of the first edition of this work have necessitated important changes in the text. To bring the book as nearly as possible up to date many deletions have been made and much new matter has been added. The articles dealing with syphilis of the circulatory system, botulism, heliotherapy, diabetes mellitus, alkalosis, spasm of the œsophagus, chronic ulcerative colitis, multiple polyposis of the intestine, jaundice, bradycardia, paroxysmal tachycardia, arterial hypotension, primary purpura hæmorrhagica, erythræmia, hæmorrhagic diseases of the newborn, trigeminal neuralgia, and tumours of the cauda equina have been rewritten. Reference to the following subjects appears for the first time: Primary meningococcic bacteriæmia, disseminated erythematous lupus, tularamia, epidemic jaundice, etiology of scarlet fever, Dick test for determining susceptibility to scarlet fever, coccidoidal granuloma, lipodystrophy, agranulocytic angina, uveoparotid fever, vasomotor rhinitis, occlusion of the coronary arteries, melanuria, Epstein's nephrosis, sickle cell anæmia, Ayerza's disease, chronic sclerosing osteitis, acrodynia and Horner's syndrome. Minor changes and elaborations occur on almost every page.

"*Dr. Stevens has succeeded in giving a succinct presentation of the various internal diseases, and in these days of increasing specialisation owing to the rapid advance of medical science on all fronts, this is no light task. His book is well adapted to the needs of the student and general practitioner. Numerous references are quoted, and wherever we have sampled its voluminous contents and checked the references given in Dr. Stevens's work, we have found evidence of a wide and accurate knowledge of recent medical literature and a wealth of clinical experience.*"—BRIT. MED. JOUR.

By A. A. STEVENS, A.M., M.D., Professor of Applied Therapeutics in the University of Pennsylvania. Octavo of 1174 pages. Cloth, 35s. net.

W. B. SAUNDERS COMPANY, Ltd. 9, Henrietta Street, LONDON, W.C. 2.

Standardised Parathyroid

PARACALCIN is standardised according to its influence on the blood calcium, e.g., 5 c.c. (or 100 units will produce an increase of 5 mg. in the blood calcium of 20 kg. dog in 15 hours.

PARACALCIN, which is the first definitely standardised parathyroid in tablet form, is put up in tablets containing gr. 1/10 of true parathyroid, 1 tablet being equivalent to 1 unit. In vials of 15 tablets.

PARACALCIN **Solution** is available in ½ c.c. ampoules, each ampoule containing 10 units.

When employing **PARACALCIN**, you will know *exactly* what dose of true parathyroid your patient actually is receiving.

ENDOCRINES LIMITED, *Sole Distributors for The Harrower Laboratory,*
And at 72, Wigmore Street, London, W. 1. **WATFORD, HERTS.**

VALENTINE'S MEAT-JUICE

In **Epidemic** and other **Diseases** of the **Tropics** in which there is great **Exhaustion,** excessive **Anaemia** and extreme **Irritability** of the **Digestive Organs, Valentine's Meat-Juice** demonstrates its **Ease of Assimilation** and **Power** in **Restoring** and **Strengthening.**

VALENTINE'S PREPARATION
NUTRIO PER ME
VOLUME 1 4/5 OZ.
MEAT JUICE
The result of an Original Process of preparing Meat and extracting its Juice by which the elements of nutrition are obtained in a State ready for immediate absorption.
DIRECTIONS. Dissolve one teaspoonful of the Preparation in three tablespoonfuls of cold or warm water; boiling water changes the character of the preparation

Albert Wilberforce Shepherd, *Glamorgan, Wales, Late District Medical Officer, Assam, India:* "I have used VALENTINE'S MEAT-JUICE in Assam, India, both in cases of Cholera and Dysentery and found it most efficacious; and in Wales, both during and after an attack of severe Influenza. I have found that in the former the stomach retained the preparation when all other things failed, and that in the latter, my patients had far less of the weakness usually complained of."

W. B. Scranton, M. D., *Medical Supt. Korean Mission Methodist Episcopal Church, Seoul, Korea:* "A most excellent use I frequently put VALENTINE'S MEAT-JUICE to, is tiding Babies through Cholera Morbus and Inanition. It acts at once and many a crisis has been passed safely, through the agency of VALENTINE'S MEAT-JUICE. It has also been of great value in my practice in the Far East in the treatment of that form of Summer Diarrhoea known as Sprue, where it tides the patients over until they can get to a better climate and the change of climate rectifies the rest."

For sale by all Chemists and Druggists.

VALENTINE'S MEAT-JUICE COMPANY
Richmond, Virginia, U. S. A.

CONCERNING THE

MEDICAL RESEARCH COUNCIL REPORT

[Diets for Boys during the School Age
by H. C. Corry Mann, O.B.E., M.D.]

"The Lancet," January 28th, 1928, comments as follows:

"MOST articles of food are poor in calcium; milk is especially rich in calcium and contains calcium and phosphates in the proper proportion. A pint of cow's milk contains one gramme of calcium, more, in fact, than is contained in a pint of lime-water. VOIT has calculated the calcium requirement of the growing child as one-third of a gramme per day; such a requirement would be covered by the consumption of 7 oz. of cow's milk."

In the preparation of CADBURY'S Dairy Milk Chocolate,* the whole of the valuable calcium and phosphates are retained. There are 1½ glasses (about 1 lb.) of fresh full cream English milk in every ½ lb. of this chocolate and even in a 2d. Bar there is half a cup of milk.

*This chocolate is sold in 1d. and 2d. Bars, 6d. Packets and ½ lb. blocks.

KOTEX

Endorsed by physicians in 48 countries

The scientific, practical, hygienic sanitary pad. Meets every medical requirement. Offers 5 unique advantages—found in no other pad in the world.

1. Absorbs 16 times its own weight in moisture instantly. Is 5 times more absorbent than the ordinary cotton-wool pad.
2. Is impregnated, by a special process, with an active deodorant.
3. Is form-fitting, secure.
4. Is light in weight, and cool.
5. Is discarded as easily as tissue.

These unique qualities ensure perfect protection and security under all circumstances—with peace of mind as a secondary, yet important consideration.

Kotex is made in a modern Canadian plant, under thoroughly hygienic conditions. And sold only in sealed, sanitary packages—to reach the user scrupulously clean.

Explanatory book and sample FREE

Fill in the coupon or pin it to your letterhead. By return you will receive a free sample of Kotex—together with an interesting, instructive and generally valuable booklet on Kotex, by G. H. Williamson, M.D.

"NEPHRITIN" BRAND. RE-ZYME GLANDULAR TABLETS

"A SHEET ANCHOR IN KIDNEY DISEASE"

COMPOSITION.—"Nephritin" is a true glandular product obtained from the cortex and convoluted tubules of young kidneys. It contains the very hormones and internal secretions of which normal kidneys make use to perform their function of freeing the body of nitrogenous waste products.

In renal disease, when the kidneys are unable properly to function, "Nephritin" will furnish the body with the identical internal secretions that are normally supplied by the kidneys.

INDICATIONS.—"Nephritin" Brand Tablets are specially indicated in acute and chronic nephritis, uræmia, albuminuria of pregnancy, eclampsia, and in other conditions in which there may be disturbances or loss of kidney function.

PACKINGS.—"Nephritin" is marketed in bottles containing 80, 500 and 1000 tablets 5 grain

"PIONEERS IN GLANDULAR THERAPY."

In the Treatment of
Pernicious Anaemia

LIVER EXTRACT B.D.H.

A highly-active powdered liver extract made in the laboratories of The British Drug Houses Limited by a process adapted from the method of Cohn and others, and tested and found efficient by The Medical Research Council.

The recent statement as to clinical results made by The Medical Research Council demonstrates the value of this highly-active product in the treatment of pernicious anæmia. After two weeks' treatment there is a marked increase in the percentage of young red cells (reticulocytes) as well as in the total number of red blood corpuscles.

Liver Extract B.D.H. is issued in glass tubes, each tube containing the equivalent of half a pound of fresh raw liver—the optimum daily dose.

Literature on request

It is now available in boxes of three and six tubes through the pharmacist or direct from the makers.

THE BRITISH DRUG HOUSES LIMITED
LONDON N-1

Liv. Ext. (1a).

Absorbs Intestinal Toxins

Over thirty-six separate poisons have been found in the intestinal tract in cases of alimentary toxemia. These consist of bile acids and alkaline wastes secreted by the intestinal mucous membrane, in addition to a variety of bacterial ptomaines and toxins.

Nujol is a highly active solvent. If it be shaken with a watery solution of indol, more than half the indol is quickly taken up. Nujol readily dissolves these waste and poisonous substances, many of which are more soluble in liquid petrolatum than in water.

Thus Nujol, which is not absorbable, takes up a very considerable portion of toxins found present in the intestinal tract and prevents their absorption into the body. The brownish colour of Nujol as seen in the stool is due to the substances which it holds in solution.

Laxatives which liquefy the intestinal contents and provoke anti-peristalsis frequently increase the absorption of intestinal toxins. Nujol not only dissolves and removes intestinal toxins, some of which are highly active poisons even in minute quantities, but also by speeding up the intestinal rate of flow it prevents their formation. Effective in all types of Constipation.

VERONIGEN

A liquid preparation of the Hypnotic Barbitone or Diethyl-barbituric acid has long been desired as a useful means of procuring sleep. When given in reasonable doses it is claimed that it does not produce any toxic symptoms whatever, nor cumulative in action, and in ordinary cases of insomnia one fluid drachm of VERONIGEN is sufficient dose for an adult. As a preventive of post-operative vomiting, one to two fluid drachms of VERONIGEN may be given one and a half to two hours before general anæsthesia is produced, and as a result much less of the anæsthetic is required. As BARBITONE has a slight diuretic action, the mixture can be used more safely than other hypnotics when the heart is weak. Where sleeplessness is a concomitant of pain, rest and relief can frequently be obtained by the administration of one drachm of VERONIGEN and two drachms of ELIXIR ACID. ACETO-SALICYLIC (Hewlett's).

DOSE FOR ADULTS.—One fluid drachm diluted, one hour before going to bed.
For Nervous Sleeplessness in Children.—10 to 20 minims diluted.

For Ill Conditions of the Gastric Tract

ALOCOL

Colloidal Hydroxide of Aluminium

"Alocol" is the practitioner's safeguard when alkaline medication is indicated. Its clearly defined antacid properties exceed those of bicarbonate of soda, magnesia and subnitrate of bismuth; furthermore, "Alocol" eliminates all the unpleasant drawbacks which are particularly feared with the usual alkalis and oxides.

When "Alocol" reaches the stomach adsorption takes place; a colloidal jelly is formed, which adhering to the walls of the stomach, diminishes their sensibility. The excess of hydrochloric acid is absorbed, but the acid reaction necessary for peptic digestion remains normal.

The advantages of "Alocol" are therefore manifest. It neither hinders proteolysis nor causes destruction of any food element or factor. Prolonged exhibition interferes in no way with the normal putrefactive function of the gastric juices or with the regular processes of nutrition.

"Alocol" is regarded as a specific in the treatment of hyperchlorhydria, whilst for all forms of fermentative dyspepsias with gastro-intestinal flatulence, acid eructations and other symptoms, common to gastric disease its influence is beneficial to the highest degree.

Complete chemical history of "Alocol" with convincing clinical reports, and supply for trial, sent free to physicians on request.

TESTOGAN

FOR MEN

Formula by Dr. Iwan Bloch.

Special Indications for Testogan.

Sexual Infantilism and Eunuchoidism in the male. Impotence and sexual weakness. Climacterium virile. Neurasthenia, hypochondria.

THELYGAN

FOR WOMEN

Formula by Dr. Iwan Bloch.

Special Indications for Thelygan.

Infantile sterility. Underdeveloped mammæ, etc. Frigidity. Sexual disturbances in obesity and other metabolic disorders. Climacteric symptoms, amenorrhœa, neurasthenia, hypochondria, dysmenorrhœa.

In ampoules for intragluteal injection, also in tablets.

Atocin

In 7½ grain Tablets.
With Aspirin
5 grains Atocin,
2½ grains aspirin.

Rheumatism

Gout, Lumbago, Neuralgic and Sciatic Conditions respond favorably to the acidum phenylcinchoninicum product: Atocin. Unsurpassed for pain-relieving qualities and as a uric acid eliminant.

ELIXIR NEUROGENIC

(Cavendish)

In the Correction of Sexual Disabilities

particularly when associated with nervous phenomena, has proven of more than ordinary worth.

Under its use the appetite improves, sleep becomes more normal, the gastro-intestinal function more regular and depression lessened.

The sexual function takes on added vigour, and the patient by degrees finds himself more capable of discharging his usual duties.

ELIXIR NEUROGENIC (CAVENDISH) is a combination of the glycero-phosphates of calcium, sodium, etc., and of strychnine glycero-phosphates.

Extensive Literature and Case Reports on request.

CHRONIC CONSTIPATION

The following striking tribute to the therapeutic value of Dimol is taken from a letter received from a distinguished member of the Medical Profession :—

"You may be interested to hear something of my patient with chronic intestinal stasis. She was a sadly-depressed, pallid, complaining person when she first came to see me. Rheumatic pains in her limbs ; inveterate constipation, which paraffin had failed to relieve ; energy which was exhausted after a few minutes of walking ; a dull, listless expression marked her cheerless life. After a fortnight of Dimol, thyroids, and magnes. sulph. as a laxative, she returned to show herself. Her eyes were bright with renewed life, her expression was alert, and she could walk easily without fatigue—to her great astonishment. The improvement in her appearance was very noticeable, and yet the constipation was traceable to an attack of scarlet fever in childhood, and is now probably associated with some intestinal change to which Sir Arbuthnot Lane has drawn attention. Dimol has proved its worth, and happiness is returning to her again."

* The efficiency of Dimol in the treatment of many other intestinal conditions of bacterial origin is conclusively told in the interesting clinical reports which, together with a brochure dealing with the pathological significance of the intestinal toxæmias, will be sent to any physician on application to the

66 TRADE MARK EPHETONIN 99 BRAND

SYNTHETIC EPHEDRINE

Replaces Adrenalin in the treatment of Bronchial Asthma, Dyspnoea, Respiratory Paralysis, Hay Fever, Hypotonia.

Conveniently issued for Oral Administration.

"EPHETONIN," like Ephedrine, when administered *orally*, acts in the same way as Adrenalin, which is only effective by injection. It marks a definite step forward in the treatment of Asthma, since it frees the patient from the hitherto necessary injections.

"EPHETONIN" exerts a more prolonged action than Adrenalin, and is less toxic. An attack of Asthma can be prevented if a dose of "EPHETONIN" be taken when the first symptoms are manifested.

Available in Ampoules also ; in this form more stable than Adrenalin

Literature and free trial specimen on application.

H. R. NAPP LIMITED, 3 & 4, Clements Inn, Kingsway, London, W.C.2.

"Opojex"

LYMPHOID SOLUTION (B.O.C.)

(Formerly named LYMPH SERUM)

Supplied in ampoules of 5, 10, 15, or 20 minims. FOR HYPODERMIC INJECTION.

This RELIABLE PREPARATION is still held in high esteem by medical practitioners who have been employing it for many years past.

Administered either alone or concurrently with "Opocaps" it is invaluable in severe cases of :—

NEURASTHENIA, MELANCHOLIA and other mental conditions.
SEXUAL IMPOTENTIA
LOCOMOTOR ATAXIA
DISSEMINATED SCLEROSIS } for the arrest of degeneration and for amelioration of symptoms.

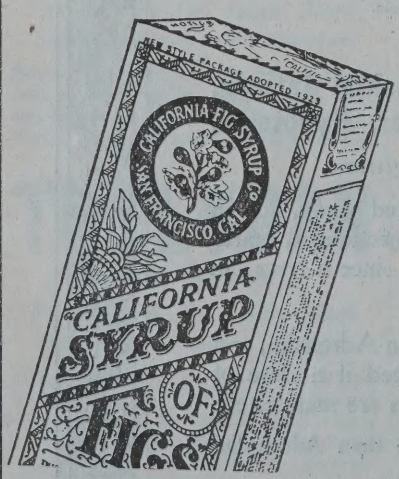
A Good Laxative



"California Syrup of Figs" merits the attention of physicians by reason of its gentle efficacy, its freedom from griping action, and its delicious flavour which makes it an ideal laxative for fastidious patients, especially juveniles.

"California Syrup of Figs" is scientifically prepared from the juice of the Black Mission Fig of California with a judicious blend of Alexandrian and Tinnevelly Senna, combined with selected aromatics to prevent griping and fermentation.

The dose is easily adjusted to the needs of the individual and will be found uniformly effective when prolonged use of a laxative is necessary.

To secure the genuine original product care should be taken to specify "*California* Syrup of Figs."

'CALIFORNIA SYRUP OF FIGS'

In bottles of two sizes : 1/3 and 2/6

EPHEDRINE

Ephedrine is an alkaloid obtained from the Chinese plant Ma Huang ⟨Ephedra⟩. Clinical trials have proved its value in cases of

Recurrent Asthma

Clinical reports also indicate its value in the prevention of fall of blood pressure in spinal anæsthesia and in influenza and pneumonia. Ephedrine is useful also in ophthalmia for the production of mydriasis.

Always Specify B.D.H.

It is important that Ephedrine should be pure and free from the alkaloid pseudo-ephedrine.

Ephedrine Hydrochloride B.D.H.

is made in the B.D.H. laboratories from Ma Huang, imported by The British Drug Houses Limited, by a special process which ensures absolute freedom from every impurity, including pseudo-ephedrine.

It is issued in tablets for oral and hypodermic use and in solution for hypodermic, intramuscular and intravenous use.

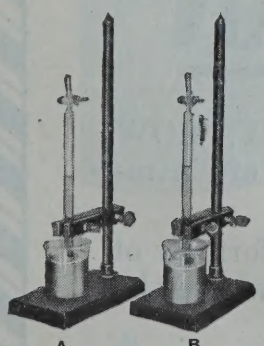
LONDON N-1

Al(2)

Dioxogen

(Trade H_2O_2 12V Mark)

means Stable Hydrogen Peroxide



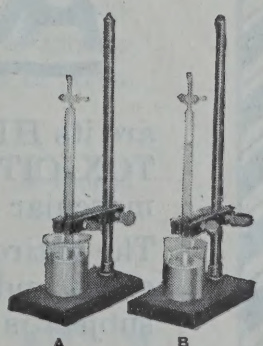
A B

Showing volumes of Oxygen liberated by (A) "Dioxogen," and (B) the same quantity of a fresh sample of ordinary Hydrogen Peroxide (10 volumes).

The merits of nascent oxygen as an antiseptic are too well known to require reiteration. The difficulty lies in obtaining a convenient and reliable source and, while Hydrogen Peroxide is most convenient in use, the unreliability, both in strength and in keeping properties, of the ordinary commercial product seriously limits its utility in practice.

"DIOXOGEN" definitely overcomes this disadvantage. Its stability is remarkable. It can be boiled or frozen without impairment of therapeutic power and, even after being kept for long periods, will yield its full volume of oxygen. This dependability of "Dioxogen" is well exemplified in the accompanying illustrations.

Descriptive literature and a clinical trial sample will be sent post free on application.



A B

Showing volumes of Oxygen liberated by the same quantity of (A) "Dioxogen" and (B) Hydrogen Peroxide (10 volumes), both having been kept for the same period.

Following Severe Disease

during which there has been considerable disturbance of metabolism, recovery frequently "hangs fire".

This is often due to an inadequate supply of the "chemical foods", calcium, sodium, potassium, manganese, phosphorus, and iron. These, together with the "dynamic" effect of small doses of quinine and strychnine, usually overcome such physiological inertia.

Compound Syrup of Hypophosphites

TRADE "FELLOWS" MARK

is the ideal form in which to administer the above, being bland, stable, non-irritating and efficient, to which 60 years of increasing use bear witness.

L.E. 12

The most satisfactory form
in which to administer Petroleum

LIQUID PARAFFIN is repugnant to many fastidious patients because of its oily, greasy character. Occasionally it causes nausea and upsets the stomach. Frequently there is leakage which prohibits its continuous use. Even when taken readily and without these drawbacks, its failure to mingle with the food and with the fecal mass, lessens its full efficacy.

ANGIER'S EMULSION is made with a specially purified petroleum of just the right degree of viscosity. It is palatable and freely taken by those who object to the plain oil; it does not nauseate or upset the stomach; it is readily miscible with water or milk; it mixes with the feces, keeping them soft and plastic and ensuring maximum lubrication; the characteristic action of petroleum is obtained with greater uniformity. Moreover, *Angier's Emulsion aids Digestion and facilitates Assimilation.*

THIRTY-SIX YEARS OF CLINICAL EXPERIENCE have demonstrated the foregoing so conclusively that countless physicians now look upon Angier's Emulsion as the most satisfactory and effective form in which to employ pure petroleum.

OVALTINE

and the Milk Diet

"Ovaltine" relieves the monotony of the milk diet.

It increases the food value by fifty per cent.

It is an effective agent for adjusting the carbohydrate deficiency of milk.

The accessory food factors are present in "Ovaltine" in correct nutritive ratio and greatly enhance the nutritional value of milk.

"Ovaltine" renders possible food concentration in small volume, a valuable feature in conditions of difficult alimentation.

By the action of its malt constituent the dense heavy curd of cow's milk is converted into light, flaky, easily digested coagulum, and it has been conclusively shown by laboratory experiment that "Ovaltine" increases the digestibility of milk two fold.

"Ovaltine" is a highly concentrated extraction of malt, milk and eggs. One cupful when made as directed has a greater food value than 3 eggs or 12 cupfuls of beef extract.

A liberal supply sent free for clinical trial on request.

The Value of HORLICK's in cases of DEBILITY is inestimable

Debility, in most instances, can be eradicated by the provision of a balanced diet.

For the patient who is run down, a dilution of 1 part of Horlick's Malted Milk to 6 or 7 parts of water will quickly restore health and vigour. In more serious cases, where debility of long standing, such as that due to years of under-feeding, malnutrition, or unbalanced dietary, is encountered, the organs may be in such a weak state that a dilution as weak as 1 to 12 will be adequate — the strength being increased every few days, as the condition of the patient improves.

There is no secret about Horlick's. It is its sheer goodness, *high nutritive value and unique digestibility*, that makes it so efficacious in all cases of debility.

It supplies in the proper ratio those elements which the body requires for the maintenance of its normal functions and for the building up of the wastage consequent upon illness.

Even the weakest patients, with virtually no energy to digest food of any kind, can assimilate Horlick's and be re-built by the ample and balanced nutriment which it affords.

For your personal use, or practical tests, it will be a pleasure for us to send you a supply upon your requirements being mentioned. Naturally no charge is made to enable those qualified to do so to test for themselves the proved excellence of our product.

Diphtheria Prophylaxis

TOXOID PREPARATIONS

IN order to produce immunity to diphtheria in individuals positive to the Schick Test, it is necessary to use, in some form, the toxin which is produced by the diphtheria bacillus. To render the toxin safe for use, it must first be deprived of its toxicity. This detoxicated toxin is known as TOXOID.

TRADE MARK 'WELLCOME' BRAND
DIPHTHERIA PROPHYLACTIC, T.A.M.
Toxoid Antitoxin Mixture

This preparation consists of toxoid plus a small amount of diphtheria antitoxin. The antitoxin was originally added as an extra safeguard. 'Wellcome' Diphtheria Prophylactic, T.A.M., has been used on a large scale in England and elsewhere for some years. It has high immunising efficiency, is non-toxic and rarely causes non-specific reactions.

TRADE MARK 'WELLCOME' BRAND
DIPHTHERIA PROPHYLACTIC, M.T.
Toxoid

In response to requests for a prophylactic containing no antitoxin, 'Wellcome' Diphtheria Prophylactic, M.T., is issued. It is free from antitoxin and consists of toxoid only.
This preparation is equal in immunising efficiency to 'Wellcome' Diphtheria Prophylactic, T.A.M. In dosage and all other respects, 'Wellcome' Diphtheria Prophylactic, M.T., can be regarded as equivalent to T.A.M., the toxoid antitoxin mixture.

These products are supplied in rubber-capped bottles of 1 c.c., 10 c.c. and 25 c.c.

CHARCOAL
BISCUITS

PATENT No. 12178

:: Awarded ::
GOLD MEDAL
LONDON 1922

"They resemble in flavour a reasonably sweet biscuit, while there is an entire absence of grittiness. The biscuits should prove useful in gastric conditions where indicated; they are conveniently packed in tin boxes, thus conserving their natural crispness. They are intended to be eaten after meals."
—(Vide THE LANCET, Dec. 17th, 1927).

Price 2/- per lb. in ¼ lb. packets, or in Tins, 2/6 and 5/- each.

SOLVING
A FOOD PROBLEM
HOVIS
the most nourishing Bread

After all the discussions as to the relative values of white, wholemeal and various brown breads it is satisfactory to have conclusive evidence at last.

Following many experiments by various research workers it is shown that no bread contains so large a percentage of Vitamin B as Hovis, or is such an active agent for healthy growth when forming the basis of the diet.

As is now well known, even a partial deficiency in Vitamin B in the diet, if lasting for any length of time impairs health and with children prevents perfect development.

Hovis even in small quantities provides sufficient vitamin in a digestive form as no other bread does, and it is liked by all.

Richest in Vitamin B

Hovis Bread consists of White Flour with the wheat germ incorporated. It is this which gives it its special value, since the germ is the part richest in the Vitamin.

The "Brownness" of bread is not a measure of its vitamin content. Further, the goodness of Hovis is fully absorbed into the system because, unlike wholemeal bread which has a tendency to pass through the body without the nourishment being properly extracted, Hovis contains no bran and is digested naturally and easily, retaining all its richness.

The evidence is conclusive. For providing the maximum of nourishment economically no bread equals Hovis.

AN IDEAL PRESENTATION *of* MAGNESIA *and* MINERAL OIL

Musterole Brand Magnesia Oil

IN the association of these two valuable internal cleansing agents, the Musterole Fine Products Co., Ltd., provide the medical profession with a remedy that overcomes all the drawbacks of mineral oil alone, and at the same time possesses certain additional advantages of its own.

Emulsified with magnesia, the oil becomes certain in action, and the risk of leakage from the bowel is avoided. The aperient action of the oil is rendered more beneficial by the antacid, absorbent and bactericidal action of magnesia.

Further, Magnesia Oil may be safely prescribed at all ages. It is pleasant to take and bland in action. It does not gripe and is entirely without unpleasant reactions. It is non-habit forming.

Like all the Musterole Brand products, Magnesia Oil is a non-secret preparation.

A full size bottle will be gladly sent free on receipt of a card. Sole distributors: Thos. Christy & Company, 4–12 Old Swan Lane, London, E.C. 4.

The Value of BOVRIL in Illness

Beef has well authenticated special powers of stimulating cellular activity, of restoring the tissues of the body and of toning up the whole system.

Bovril contains these powers in a highly concentrated, effective and digestible form. That is why Bovril—or Invalid Bovril, which is prepared specially without seasoning—has been recommended for years by the Medical profession to meet the extra demands of enfeebled systems during convalescence.

BOVRIL Limited cordially invite any medical man to visit and inspect their factory at any time.

148-166, Old Street, London, E.C.1.

Experience has proved you cannot advise a Better Food

"Berina" Malted Milk is a valuable diet in cases of digestive derangement, gastritis, chronic intestinal catarrh, gastric ulcers, etc. It can be tolerated by the most delicate stomach, and while most palatable, its flavour will not cause distaste although used over long periods.

Write for full particulars and samples to MONTGOMERIE & CO., Ltd., Fairley St., Ibrox, Glasgow.

IRVING'S YEAST-VITE TABLETS

The New Yeast Vitamin Treatment.

We hold high medical testimony showing efficacy in cases of **SEPTICÆMIA, PYÆMIA,** skin blemishes and other disorders of the blood.

They act with quick stimulating effect on the pancreas, liver and kidneys.

The antipyretic, anodyne and analgesic action is more pronounced than that of the usual coal tar derivatives, without unfavourable reaction, and have the advantage of rapid assimilation.

Of value as a vitaliser and rejuvenator.

Recommended as a nerve sedative, and of considerable value in moderating menstrual and labour pains.

We supply (without charge) to physicians, hospitals, clinics and nurses sufficient supplies for exhaustive tests.

IRVING'S YEAST-VITE LABORATORIES,

12/16, LAYSTALL STREET, CLERKENWELL, LONDON, E.C. 1.

WHOOPING COUGH

The best practice in the treatment of whooping cough recognizes the importance of keeping the patient out of doors as much as possible. The food should be easily digestible, nourishing and given a little at frequent intervals.

There are no specifics for this disease. In very young children drugs are administered with difficulty and are of uncertain effect.

Vaporized Cresolene at night will be found a simple and effective means of preventing the paroxysms at that time, thus tending to preserve the strength of the patient, avoid complications, and hasten convalescence.

ST. ANDREW'S HOSPITAL

FOR MENTAL DISORDERS,

NORTHAMPTON

FOR THE UPPER AND MIDDLE CLASSES ONLY.

PRESIDENT: THE MOST HON. THE MARQUESS OF EXETER, C.M.G., C.B.E.

MEDICAL SUPERINTENDENT: DANIEL F. RAMBAUT, M.A., M.D.

This Registered Hospital is situated in 120 acres of park and pleasure grounds. Voluntary Boarders, persons suffering from incipient nervous and mental disorders, as well as certified patients of both sexes, are received for treatment. Careful clinical, bio-chemical, bacteriological and pathological examinations. Private rooms with special nurses, male or female, in the Hospital or in one of the numerous villas in the grounds of the various branches can be provided.

RECEPTION HOSPITAL

There is a Reception Hospital, in detached grounds with a separate entrance, to which patients and voluntary boarders can be admitted. It is equipped with all the apparatus for the most modern treatment of Mental and Nervous Disorders. It contains special departments for hydrotherapy by various methods, including Turkish and Russian baths, the prolonged immersion bath, Vichy Douche, Scotch Douche, Electrical baths, Plombières treatment, &c. There is an Operating Theatre, a Dental Surgery, an X-ray Room, an Ultra-violet Apparatus, and a Department for Diathermy and High Frequency treatment. It also contains Laboratories for bio-chemical, bacteriological, and pathological research.

MOULTON PARK

Two miles from the Main Hospital there are several branch establishments and villas situated in a park and farm of 650 acres. Milk, meat, fruit and vegetables are supplied to the Hospital from the farm, gardens and orchards of Moulton Park. Occupation therapy is a feature of this branch, and patients are given every facility for occupying themselves in farming, gardening, and fruit growing.

BRYN-Y-NEUADD HALL

The Seaside house of St. Andrew's Hospital is beautifully situated in a Park of 330 acres, at Llanfairfechan, amidst the finest scenery in North Wales. On the North West side of the Estate a mile of sea coast forms the boundary. Voluntary Boarders or Patients may visit this branch for a short seaside change or for longer periods. The Hospital has its own private bathing house on the seashore. There is trout-fishing in the park.

At all the branches of the Hospital there are cricket grounds, football and hockey grounds, lawn tennis courts (grass and hard court), croquet grounds, golf courses and bowling greens. Ladies and gentlemen have their own gardens, and facilities are provided for handicrafts such as carpentry, &c.

For terms and further particulars apply to the Medical Superintendent (TELEPHONE: No. 56 Northampton) who can be seen in London by appointment.

The Belgrave Hospital for Children

(Incorporated), 1, Clapham-road, S.W. 9.

The Committee of Management invite applications for the posts of

HOUSE SURGEON and
ASSISTANT HOUSE PHYSICIAN,

which will become vacant on April 30th. Applicants (men) must be fully qualified and registered. The appointments are for six months, with board, residence, and washing provided. Salary at the rate of £100 per annum in each case.

Applications, with copies of testimonials, stating age, to be forwarded on or before Wednesday April 11th.

By order.
THOMAS CLAPHAM, Secretary.

Ministry of Health.

APPOINTMENT OF DEPUTY REGIONAL MEDICAL OFFICERS.

The Minister of Health invites applications from registered Medical Practitioners for appointment as Deputy Regional Medical Officer on the Staff of the Ministry in various parts of England, for the discharge of combined Clinical and Administrative duties in connection with the National Health Insurance Medical Service.

The rate of remuneration will be £800 per annum, rising by annual increments of £30 to a maximum of £1100. No cost of living bonus will be payable in addition thereto.

Successful candidates under the age of fifty years will be appointed to this scale and will be established Civil Servants, with the usual pension rights. Those who are considered to possess exceptional or special qualifications may be allowed to enter the above scale at a commencing salary of £850 per annum.

Successful candidates of the age of fifty years and upwards (at the time of appointment) will be appointed to the above scale and will receive unestablished, non-pensionable appointments. In special circumstances, where a candidate in this category has special qualifications and experience, the commencing salary might be advanced to a point in the scale not exceeding £1000 per annum inclusive.

Above the grade of Deputy Regional Medical Officer there are at present thirty posts of Regional Medical Officers rising to a maximum of £1400 a year inclusive, and four posts of Divisional Medical Officers rising to a maximum of £1600 a year inclusive. The above numbers are, however, subject to revision from time to time as the exigencies of the Service may determine. When vacancies are to be filled among the Regional Medical Officers, preference will be given to those who have given satisfaction as Deputy Regional Medical Officers.

Candidates must be Medical Men of not less than ten years' standing and not exceeding the age of fifty-five years, with a wide experience of General Practice, especially amongst the industrial population. Preference will be given to candidates who served in His Majesty's Forces during the War.

Deputy Regional Medical Officers are required to devote their whole time to the public service and to perform such duties as may be assigned to them by the Minister from time to time. These include acting as deputy to the Regional Medical Officer in the work carried out by the latter :—

(*a*) as Medical Referee in cases of insured persons referred for a second medical opinion on questions of incapacity for work, or of restoration of working capacity ;
(*b*) in assisting in the administration of the Insurance Medical Service.

Deputy Regional Medical Officers must be prepared to reside in the area from time to time assigned to them.

Canvassing Members of Parliament or officers of the Ministry will render a candidate liable to disqualification.

Forms of application, with further particulars of the appointment, may be obtained from the

DIRECTOR OF ESTABLISHMENTS,
Ministry of Health,
Whitehall, S.W.

No application can be considered unless received *on the prescribed form* not later than the 16th April, 1928.

Walsall Union.

MEDICAL OFFICER.

Applications are invited from fully qualified registered Medical Practitioners for the appointment of a whole-time Resident Medical Officer at the Poor Law Institution, Walsall.

The total number of beds in the Institution is 629, of which 193 are in the Hospital.

Applicants must not be more than 40 years of age. The remuneration will be at the rate of £600 per annum, plus fees for Vaccination, and the certification of lunatics. A separate residence within the confines of the Guardians, estate will be provided, rent, rates, and taxes free, together with fuel, lighting and heating.

The appointment is subject to the provisions of the Poor Law Officers' Superannuation Act, 1896, for which purpose the valuation of the emoluments will be fixed at £150 per annum.

The person appointed will be required to commence duty on or about the 1st July, 1928.

Applications, stating whether married or single, age, experience and qualifications, accompanied by copies of recent testimonials, should be sent to me not later than 21st April, 1928.

Canvassing the Guardians directly or indirectly will be a disqualification.

C. S. FOTHERGILL, Clerk to the Guardians.
Union Offices, 29, Leicester-street, Walsall, 24th March, 1928.

County Borough of Walsall.

APPOINTMENT OF CLINICAL TUBERCULOSIS OFFICER, ASSISTANT MEDICAL OFFICER OF HEALTH, AND ASSISTANT SCHOOL MEDICAL OFFICER. (Male).

Applications are invited from medical men not over the age of thirty-five for the appointment of a Clinical Tuberculosis Officer and Assistant Medical Officer of Health, &c.

Salary £750 per annum.

Applicants must be duly registered medical practitioners holding a Diploma of Public Health, and should have had at least six months' experience since graduation as House Physician or House Surgeon in a General Hospital together with special experience of Tuberculosis in Dispensary and Sanatorium practice.

A knowledge of Bacteriology is essential.

Applications on forms to be obtained from the undersigned, stating age, qualifications, training and experience, together with copies of three recent testimonials and endorsed on the envelope "Clinical Tuberculosis Officer" should be sent to the Town Clerk not later than Wednesday, the 11th April, 1928.

The person appointed will be required to devote the whole of his time to the duties, to reside in Walsall, and to act under the administrative control of the Medical Officer of Health.

The appointment will be subject to the provisions of the Local Government and Other Officers' Superannuation Act, 1922.

Canvassing directly or indirectly will be considered a disqualification.

HERBERT LEE, Town Clerk.
Council House, Walsall, 22nd March, 1928.

Rhondda Urban District Council

ASSISTANT MEDICAL OFFICER.

The above Council invite applications from registered medical practitioners to act as whole-time Assistant Medical Officer of Health and Assistant School Medical Officer under the direction, supervision, and control of the Council's Medical Officer of Health, at a salary of £600 per annum, together with travelling expenses necessarily incurred in the performance of the duties.

Candidates must have had not less than three years' professional experience subsequent to registration and the possession of a Diploma in Public Health is desirable.

The duties will pertain to both the public health and school medical services, but experience in the prescription of glasses for errors of refraction, of the examination and certification of mentally defective children, the administration of anæsthetics in minor (including dental) operations, and orthopædic work will be considered to be of special importance.

The appointment will be subject to two calendar months' notice on either side, and to the approval of the Board of Education. The officer appointed will be required to reside within the Rhondda Urban District and will not be allowed to engage in private practice.

Canvassing by or on behalf of candidates will be considered to be a disqualification.

Applications are to be made on forms obtainable from the Medical Officer of Health, Tydfil House, Llewellyn-street, Pentre, Rhondda, by whom they must be received, endorsed "Assistant Medical Officer," and accompanied by copies of three recent testimonials, not later than Wednesday, April 11th, 1928.

D. J. JONES, Clerk of the Council.
The Council Offices, Pentre, Rhondda, 21st March, 1928.

BOVRIL MEDICAL AGENCY, Ltd.

ALDINE HOUSE,

10-13, BEDFORD STREET, STRAND, LONDON, W.C.2.

Telegrams: BOVMEDICAL, WESTRAND-LONDON. *Telephone:* GERRARD 3543 (3 Lines).

Under the personal direction of Dr. J. FIELD HALL and Mr. J. C. NEEDES,
who have both had many years' experience as Medical Transfer Agents.

The commission chargeable in respect of any Practice or Partnership in Great Britain placed exclusively in the hands of this Agency has been fixed on an exceptionally favourable scale, the maximum chargeable on any transfer being fifty pounds (£50).

NO CHARGE IS MADE TO PRINCIPALS FOR THE INTRODUCTION OF LOCUM TENENS OR ASSISTANTS.
Accountancy and Legal Services furnished by the Agency, where desired, at moderate inclusive charges.

PRACTICES AND PARTNERSHIPS FOR SALE.

1. SUFFOLK.—Coast Town.—DEATH VACANCY.—Old-estab. mainly better-class PRACTICE, situated in select Seaside resort. Cash receipts average £2500 p.a. (last year £2700), including panel of over 800. A few small appts. Very little Midwifery. Good house, with ample accommodation. Up-to-date Cottage Hospital. Sport of all kinds, and very good schools. Excellent locum in charge. Premium 1½ years' purchase.
2. KENT.—Favourite Coast Town.—Old-estab., very sound, mixed-class PRACTICE, averaging for the past three years over £2500 p.a. Fees from 4s. to 21s. Very little Midwifery, from 5 gns. Convenient house with good professional accommodation, 2 reception, 3 bedrooms, &c. Electric light. Garage. Price for lease (with 20 years to run at a ground rent of £37), £200. Premium 1½ years' purchase.
3. SUSSEX.—Within ten miles of Seaside Resort.—Old-estab. Mixed-class PRACTICE, situated in small, very attractive country town (pop. nearly 3000 with large surrounding district) amidst beautiful scenery. Receipts for past 3 years average £2792 p.a., including panel of over 2000, and union and vaccination appts. Good house with surgery, waiting-room, and dispensary, 3 reception, 7 bedrooms, &c. Garden and garage. Electric light. Price £3000, £2000 on mortgage at 6 per cent. Premium £4500.
4. SOUTH DEVON.—Very pleasant small town, within easy reach of the Sea.—Old-estab. Mixed-class PRACTICE. Average income for the last 3 years over £2000, including panel of 600. Fees 5s. to 21s. with a few at 3s. 6d. Exceptionally good house, with ample accommodation, half an acre of garden, &c. Electric light. Excellent sport, schools and social life. Premium for house and Practice, £4500.
5. SUSSEX.—Coast Town.—Very old-estab. Middle-class PRACTICE. Average income for the last 2 years about £1350, including over £500 from panel. Fees 2s. 6d. to 7s. 6d., a few at 10s. 6d. Little Midwifery. Good, well-situated house. Price for freehold £1200. Prem. £2000.
6. MIDLANDS.—Country Town within easy reach of County Town.—Old-estab. PRACTICE, offering large scope. Average income for last 3 years £1367, including panel of over 800. Opposition slight. Fees 3s. 6d. to 10s. 6d. Very convenient house, with 2 reception, 7 bedrooms and professional rooms. Electric light. Garage. Garden. Price £1500, £1000 on mortgage. Prem. 1½ years' purchase.
7. NORTH-WEST OF ENGLAND.—Large town, near Coast. Very old-estab. mixed general PRACTICE, held by the Vendor for nine years. Income for last year over £2700, and increasing. Panel of about 840. No appointments. Fees 3s. 6d. to 10s. 6d. Very little midwifery from 3 gns. Exceptionally good well-situated house; will be let on lease. Considerable scope for electro-therapeutic and ear, nose, and throat work, and some surgery. Premium 1½ years' purchase, part by arrangement.
8. SOUTH MIDLANDS.—County Town.—PARTNERSHIP.—A two-fifths share is for disposal owing to retirement of junior partner in a well-estab. middle- and working-class PRACTICE. Income immediate past twelve months over £2700, including panel of 1368. Fees 2s. 6d. to 10s. 6d. Suitable house, with 4 bedrooms, &c. Nice garden. Rent £115 p.a. Premium 2 years' purchase.
9. PARTNERSHIP WITHIN TEN MILES OF LONDON—open healthy suburb.—A share producing at first £1000, with increase to £1700 in 3 years, is for disposal in an extensive old-estab. Practice. Appts worth £340, and very large panel. Good house with garden, at moderate rent. Premium 2 years' purchase.
10. EASTERN COUNTIES.—Old-estab. unopposed country PRACTICE, in rich agricultural practice, near sea, averaging for the past 3 years nearly £1800 p.a. (last year £1897) including panel of 770. Nearest opposition 5 miles; visits 5s. to 10s. Mid. 2 to 3 gns. Good house (consulting and waiting rooms, 3 reception, 6 bedrooms, bathroom, &c.), with garden, tennis court, garage, &c. Rent on long lease £80 p.a. Premium £2400, or near offer.
11. MANCHESTER.—Rapidly developing outlying suburb.—Good middle- and working-class PRACTICE, increasing and producing for the last 12 months over £1500. Panel of 700. Fees from 3s. 6d. Particularly good house, specially built, and containing 3 reception, 5 bedrooms, &c. Electric light. Garden, garage. Price £3550, part on mortgage. Premium £2250.
12. SOUTH COAST.—Favourite Resort.—Old-estab. non-panel and non-dispensing PRACTICE, producing over £1000 p.a., and offering large scope. Fees 10s. 6d.; a few at 7s. 6d. Excellent, well-situated house; rent £130 on lease. Premium £1500.
13. ESSEX COAST.—Favourite Resort.—PARTNERSHIP.—A one-third share, to commence with, in an old-estab. Middle-class Practice. Average income of about £2800. Panel of 600. Visits 4s. 6d. to 21s. Little Midwifery. Suitable accommodation can be obtained. Premium 2 years' purchase.
14. NORTH WALES.—Very pleasant coast town.—Good middle- and working-class PRACTICE. Income over £1800 p.a. including panel of 850. Fees 3s. 6d. to 15s. Good house, beautifully situated facing sea, with 3 reception, 4 bedrooms, &c. Garage for 2 cars. Rent on lease £30 p.a. Sport of all kinds and schools. Premium 1½ years' purchase.
15. NORTH AFRICA.—Well-estab. unopposed English General PRACTICE, good class and worth about £1000 p.a. Good fees and little Midwifery. Living expenses exceptionally small. Large commodious up-to-date house. Electric light. Garage. Inclusive rent £108 p.a. Easy reach London and Marseilles. Premium (to include entire contents of house, all surgical instruments, appliances and medical books, &c.) £2000.
16. NORTH-EAST COAST.—PARTNERSHIP.—A one-third share in an old-estab. mixed Practice, situated in a growing seaside resort. Income this year at the rate of £2400 including panel of over 1000. Fees from 3s.6d. Suitable house with 2 recep., 6 beds. Rent on lease £62 10s. Good scope for surgery and midwifery. Prem. 2 years' purchase.
17. CENTRAL WALES.—Good Hospital Town.—Old-estab. non-dispensing PRACTICE. Income over £1400, including £130 from appts. and panel of 500. Fees 5s. to 42s. Little midwifery. Good house in centre of town, with pleasant garden. Price for freehold £1500. Premium £2100. Exceptional scope for surgery.
18. PARTNERSHIP.—Very attractive small town in the South-West of England, and within 20 miles of the Sea. A half-share is offered in an old-estab. good mixed-class Practice, with large scope. Present income over £2600, including panel of nearly 1000. Fees from 2s. 6d. to 21s. Suitable house available, on rental or for sale. Prem. 2 yrs.' purchase.
19. WITHIN FIFTEEN MILES OF LONDON.—Good Residential district.—Old estab. non-dispensing, non-panel, mainly Middle-class PRACTICE. Average income for past three years nearly £4000. Fees chiefly 10s. 6d. to 42s. Midwifery from 10 gns.; only few cases. Good house with 3 reception, 5–6 bedrooms, &c.; ½ acre of garden. Premium 1½ years' purchase.
20. HOME COUNTIES.—PARTNERSHIP.—A one-fourth share, to commence with, in a very old-estab. mixed-class Practice, comprising many good families. Income for the past twelve months at the rate of £2900. Fees 2s. 6d. to 21s. Suitable house available; price about £1600. Sport of all kinds and plenty of schools. Premium £1600, £1000 down and balance by instalments. Oxon or Cantab Graduate preferred.
21. LANCS.—Large Town.—PARTNERSHIP, with Succession as agreed. A one-fourth share in the first year, with increase later, in an old-estab. mixed general practice. Income for the immediate past year over £2400, including panel of nearly 1000. Fees 2s. 6d. to 10s. 6d. Very little Midwifery. Large Hospital and prospects of vacancy. Graduate preferred. Premium 1½ years' purchase.
22. YORKS.—(North Riding).—In a pleasant market town, an old-estab. PRACTICE averaging nearly £1400 p.a. (last year £1547), including panel of 780. Visits 3s. 6d. upwards, medicine extra. Good house, 2 reception, 6 bedrooms, &c., central heating. Garden, small orchard. Garage. Rent £75 p.a., or would be sold for £1800. Premium 1½ years' purchase £1000 down.

Full Schedule of Terms and Conditions will be forwarded on application

British Medical Bureau

(THE SCHOLASTIC, CLERICAL & MEDICAL ASSOCIATION LTD.)

(Founded 1880)

Tele Address: Triform, Wesdo—London. **12, Stratford Place, Oxford Street, W.1.** Telephone: Mayfair 1782 1783

The Association has long been favourably known to the members of the Medical Profession as a thoroughly trustworthy and successful Agency for the transaction of every description of Medical, Scholastic and Accountancy business, and the British Medical Association has every confidence in recommending its members to consult Mr. A. V. STOREY, the General Manager, in all transactions requiring the services of a Medical Agent.

MEMBERS OF THE BRITISH MEDICAL ASSOCIATION MAY TAKE ADVANTAGE OF A REDUCED SCALE OF CHARGES APPLICABLE TO THEM.

For the sake of reference the business undertaken by the BRITISH MEDICAL BUREAU is divided under the following heads:—

TRANSFER OF PRACTICES, PARTNERSHIPS, etc.

Medical Practitioners wishing to dispose of Practices, or desiring to take Partners, are advised to negotiate the business through the BRITISH MEDICAL BUREAU. Vendors may depend upon receiving introductions only to eligible and bona fide purchasers. All information is treated in strictest confidence.

Full and trustworthy information regarding Practices, Partnerships, etc., for disposal, supplied gratis to Purchasers.

ASSISTANTS AND LOCUMTENENTS.

Assistants and Locumtenents can be secured at short notice. It is the foremost aim of the BRITISH MEDICAL BUREAU to ensure that only the most TRUSTWORTHY AND RELIABLE Locums and Assistants are sent out.

RESIDENT PATIENTS.

Medical Men wishing to receive Resident Patients should enrol their names on the books of the BRITISH MEDICAL BUREAU. A large number of Patients are placed yearly through this medium.

ACCOUNTANCY.

The BRITISH MEDICAL BUREAU has its own staff of fully qualified Accountants wholly engaged on Medical work, i.e., Investigation of Practices for purchasers, Income Tax, Auditing books and accounts, etc.

SCHOLASTIC DEPARTMENT.

Medical Men will find this Department of the BRITISH MEDICAL BUREAU of great assistance in the selection of Educational Establishments, Private Tutors, Governesses, etc. Prospectuses and advice gratis.

All correspondence and applications should be addressed to **A. V. STOREY, General Manager.**

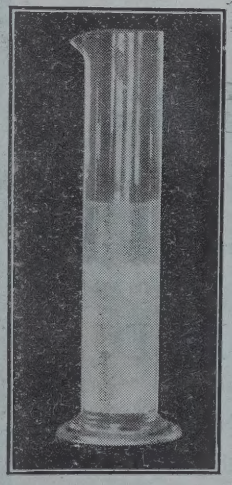
'Allenburys' The DIET

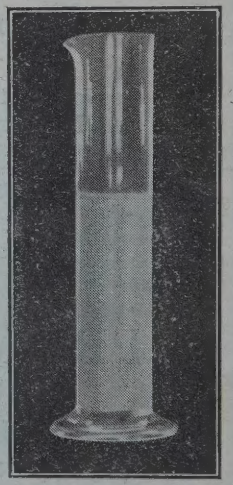
A Stimulating and Sustaining Food Beverage



A Showing the heavy curd formed by the action of gastric juice on ordinary cow's milk.

A solution to the problem of feeding in many acute and chronic affections is found in the use of the 'Allenburys' Diet, which presents distinct advantages over cow's milk both with regard to food value and digestibility. The 'Allenburys' Diet is a palatable and highly nutritive food beverage prepared from pure fresh full-cream milk and whole wheat, and is particularly easy of assimilation. It replaces with advantage milk and the milk dishes commonly employed in sickness and convalescence and can often be taken and retained where other foods are rejected. As a stimulating and sustaining beverage for people of all ages, it is infinitely superior to tea, coffee, etc. It can be made in a minute simply by adding either boiling water or milk.

In tins at 2/1, 4/- and 7/6.



B Showing the finely flocculent curd formed by the action of gastric juice on the 'Allenburys' Diet.

Descriptive Literature and free clinical sample will be gladly sent on request.
